#### **EXECUTIVE SUMMARY**

This report documents the Site Investigation (SI) activities conducted at Site 12 - Ramp Area and Site 13 - Motor Vehicle Maintenance Facility (MVMF) of the South Dakota Air National Guard (SDANG), Joe Foss Field, Sioux Falls, South Dakota, for the Air National Guard Readiness Center (ANG). Figure ES-1 shows the location of Joe Foss Field.

#### INTRODUCTION

The SDANG facilities occupy 166 acres in the southern portion of Joe Foss Field, the municipal airport for Sioux Falls, as shown in Figure ES-2. The Ramp Area (Site 12) and the MVMF (Site 13) are located within the SDANG facilities, as Figure ES-3 shows. The Ramp Area is used for refueling, taxiing, and parking aircraft. During routine repairs to the ramp in 1993, fuel-contaminated soils were discovered underneath parts of the ramp. Approximately 1,542 tons of petroleum-contaminated soil have been removed from the contaminated areas. The MVMF was constructed in 1976 and consists of an automotive maintenance shop (Building 11) and a fuel dispensing station near the building. Three 2,000-gallon above-ground fuel tanks and buried lines from the tanks to the dispensing pumps are located at Site 13. The fuel lines were tested for leaks in 1993 and 1994, and no leaks were detected during either test. Soil contamination was observed when concrete warning posts were being installed around the fuel dispensing island in July 1994.

#### FIELD PROGRAM

The objective of this SI was to confirm the presence or absence of petroleum and/or solvent contamination in subsurface soils and groundwater at Sites 12 and 13. The field activities conducted during the SI consisted of:

- A soil organic vapor (SOV, or "soil gas") survey
- Sampling soils and groundwater using a hydraulic probe
- Screening soil and groundwater samples for volatile organic compounds (VOCs), including benzene, toluene, ethylbenzene, and xylenes (BTEX), total petroleum hydrocarbons (TPH), and eight organic solvents (Site 13 only) in the field

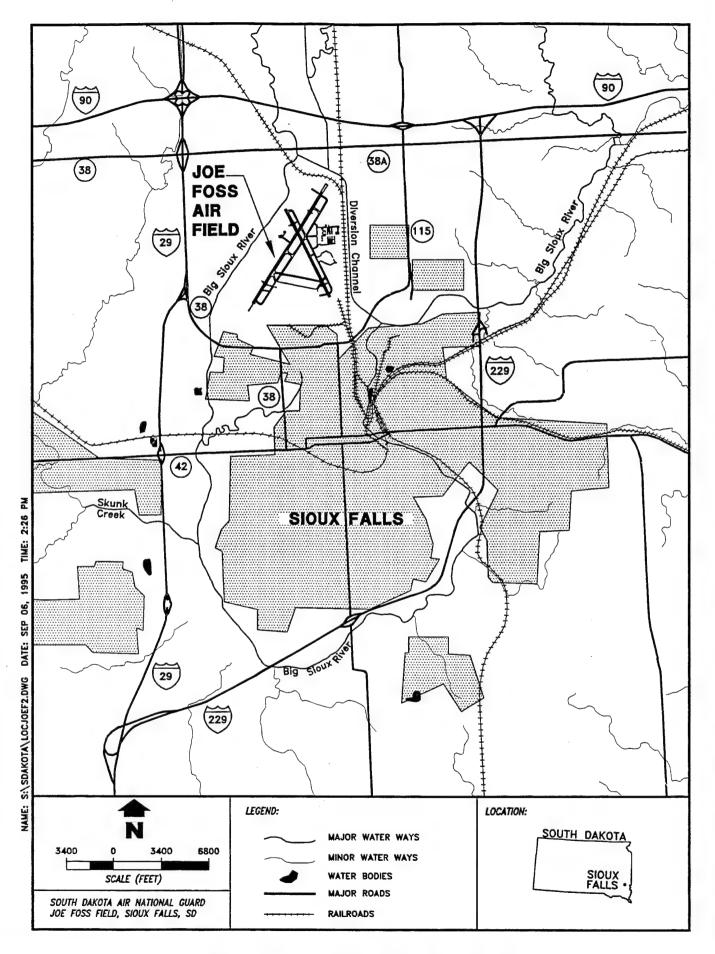

Figure ES-1. Location of Joe Foss Airfield

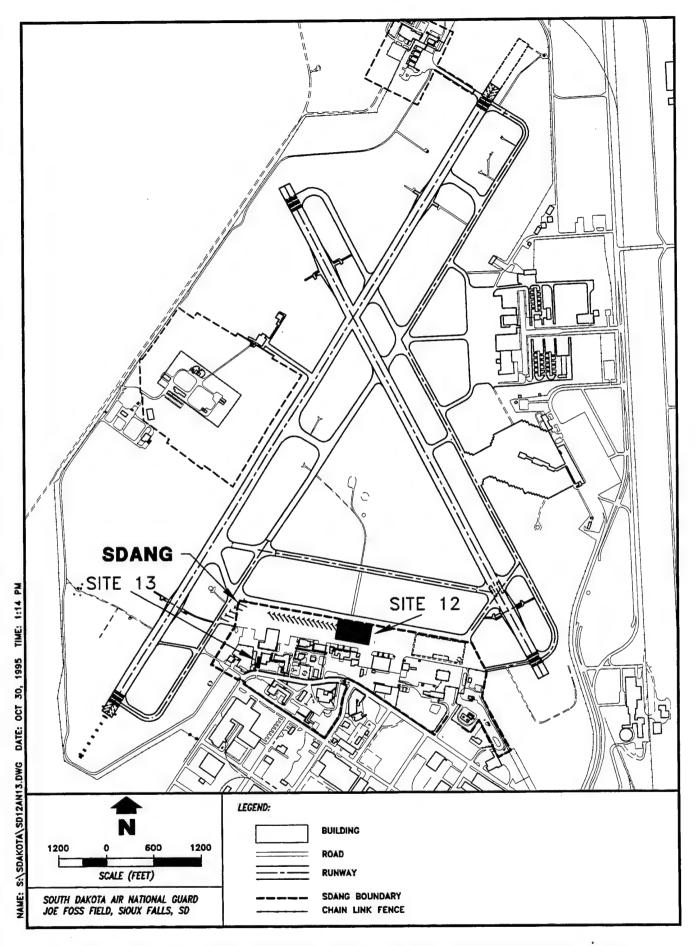

Figure ES-2. Location of SDANG within Joe Foss Airfield and Sites 1 and 3

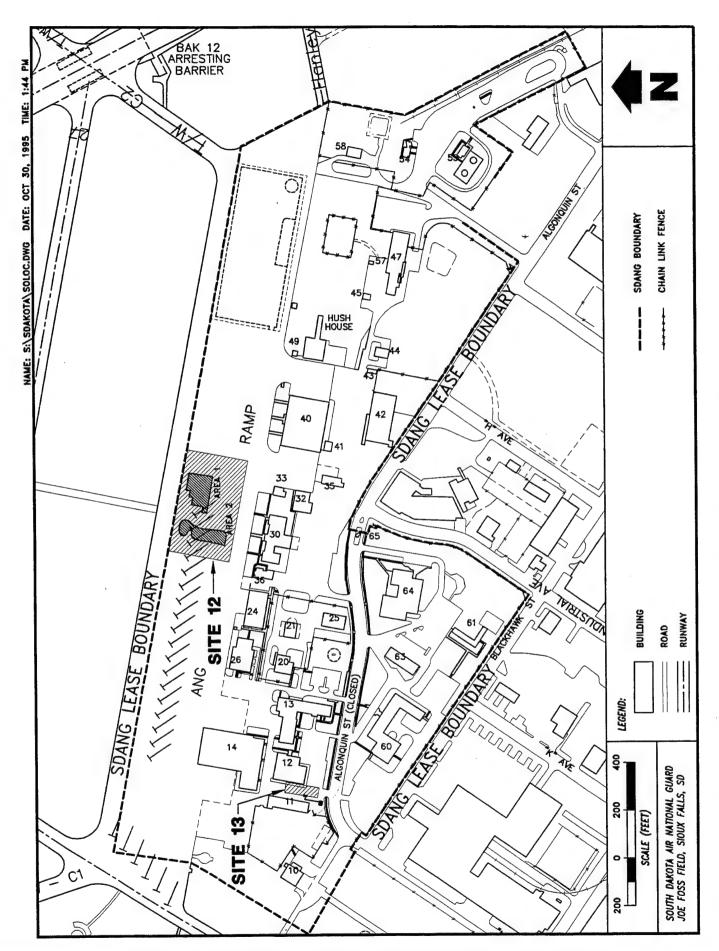

Figure ES-3. Location of Sites 12 and 13, and Sites 8, 9, 10, and 11

- Laboratory analysis of soil and groundwater for BTEX and TPH at both Sites 12 and 13 and for eight organic solvents at Site 13
- Installing six groundwater monitoring wells and three piezometers to monitor water quality and assess groundwater flow direction.

#### SITE INVESTIGATION RESULTS

Isolated low-level soil contamination was detected during the screening of soil gas and soil samples at Site 12 - Ramp Area. TPH was detected in both soil gas and soil samples at three locations. Two of these locations are east of Area 1. The third location is the northwest corner of Site 12. The maximum concentration of TPH in soils was 10 mg/kg (10 parts per million [ppm]). Ethylbenzene and xylenes were detected in soil gas at two depth intervals at a sampling location east of Area 1. These compounds were not detected in soil samples.

Groundwater samples from five monitoring wells were analyzed for TPH and BTEX. TPH was detected at 81  $\mu$ g/L in MW12-1. This well was drilled at a soil gas/soil sampling and groundwater screening point where TPH was present above detection limits, east of Area 1. No other compounds were detected in groundwater.

BTEX, TPH, and solvents were not detected in soil and soil gas samples screened at Site 13 - MVMF. Low-level contamination from BTEX, TPH, and solvents was detected immediately around the pump island. BTEX compounds were identified at three locations east, north, and west of the pump island. BTEX, TPH, or solvents were not detected in groundwater in the monitoring well installed at Site 13.

#### CONCLUSIONS AND RECOMMENDATIONS

Site 12 - Ramp Area—BTEX and TPH were detected in soil gas samples collected immediately east of Area 1. The highest concentrations of soil vapors were detected around a single point east of Area 1. The soil gas detections seem to be most areally extensive in the 6- to 8-foot sampling interval (approximately 9,000 square feet).

TPH was detected in low concentrations in soil samples at two out of five sampling locations during field screening. During laboratory analysis of soils for BTEX and TPH, TPH was present above detection limits at one location. This sampling point coincides with the SOV point showing the maximum concentrations in soil gas.

TPH was detected during groundwater screening by the offsite laboratory at the point where maximum concentrations of soil gas were detected. BTEX compounds were not detected during the groundwater screening. During groundwater analysis of the five monitoring wells, TPH was detected in low concentrations at the well location coinciding with the SOV point previously mentioned.

These findings indicate that isolated areas of soil and groundwater contamination are present at Site 12. TPH contamination in soils may be impacting groundwater quality at Site 12 east of Area 1. TPH was detected in one monitoring well; however, the groundwater results do not indicate TPH migration. Isolated soil and groundwater contamination occur at levels below South Dakota Department of Environment and Natural Resources (DENR) cleanup standards and maximum contaminant levels (MCLs), respectively. One groundwater sample contained TPH in excess of the South Dakota standard for TPH in wellhead protection areas.

Based upon these findings, it is recommended that groundwater monitoring at Site 12 continue under a quarterly monitoring program. Continued monitoring will expand the data set for groundwater at Site 12, allowing ANGRC to determine temporal and spatial variations in TPH concentrations. The data should allow ANGRC to evaluate whether soil contamination east of Area 1 sufficiently impacts groundwater to warrant further study.

Site 13 - Motor Vehicle Maintenance Facility—BTEX, TPH, or solvents were not detected during the SOV survey or onsite soil screening at Site 13. Soils at four locations within Site 13 were analyzed in the laboratory and BTEX, TPH, or solvents were not detected.

BTEX compounds were detected in low concentrations at three groundwater screening locations in the immediate area of the pump island. TPH and solvents were not present above

detection limits. BTEX, TPH, and solvents were not present above detection limits during groundwater analysis of monitoring well GW13-1, located downgradient from the screening samples.

The Site 13 SI data indicate that isolated soil and groundwater contamination occur at levels below the South Dakota DENR cleanup standards and MCLs, respectively. Therefore, no further action is recommended for this site. A decision document recommending no further action should be prepared for Site 13.

THIS PAGE WAS INTENTIONALLY LEFT BLANK

#### 1. INTRODUCTION

This report documents the Site Investigation (SI) activities conducted at Site 12 - Ramp Area and Site 13 - Motor Vehicle Maintenance Facility (MVMF) of the South Dakota Air National Guard (SDANG), Joe Foss Field, Sioux Falls, South Dakota, for the Air National Guard Readiness Center (ANG). The SI activities were completed under National Guard Bureau (NGB) Contract No. DAHA90-94-D-0007. The SI field activities were conducted in June and July 1995 by Science Applications International Corporation (SAIC) and were accomplished in accordance with the SI Work Plan (SAIC 1995). The following sections present background information, the purpose and scope of the SI, and the methodology used for the investigation.

#### 1.1 BACKGROUND

The Environmental Restoration Program (ERP) was established in 1984 to promote and coordinate efforts for the evaluation and cleanup of contamination at U.S. Department of Defense (DOD) installations. On January 23, 1987, Presidential Executive Order 12580 was issued, which assigned responsibility to the Secretary of Defense for carrying out ERP within the overall framework of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and the Superfund Amendments and Reauthorization Act (SARA). The Installation Restoration Program (IRP) was established under ERP to identify, investigate, and clean up contamination at DOD installations. The IRP is focused on cleanup of contamination associated with past DOD activities to ensure that risks to public health are eliminated and to restore natural resources for future use. ANG manages the IRP and related activities.

SDANG is located at Joe Foss Field, the municipal airport in Sioux Falls, in southeast South Dakota, as shown in Figure 1-1. SDANG was established in 1946 to provide air combat preparedness. The facilities at SDANG, including aircraft hangers, administrative buildings, and vehicle maintenance facilities, occupy 166 acres on the southern edge of Joe Foss Field, as shown in Figure 1-2. Joe Foss Field sits on the floodplain between the Big Sioux River and engineered diversion channels.

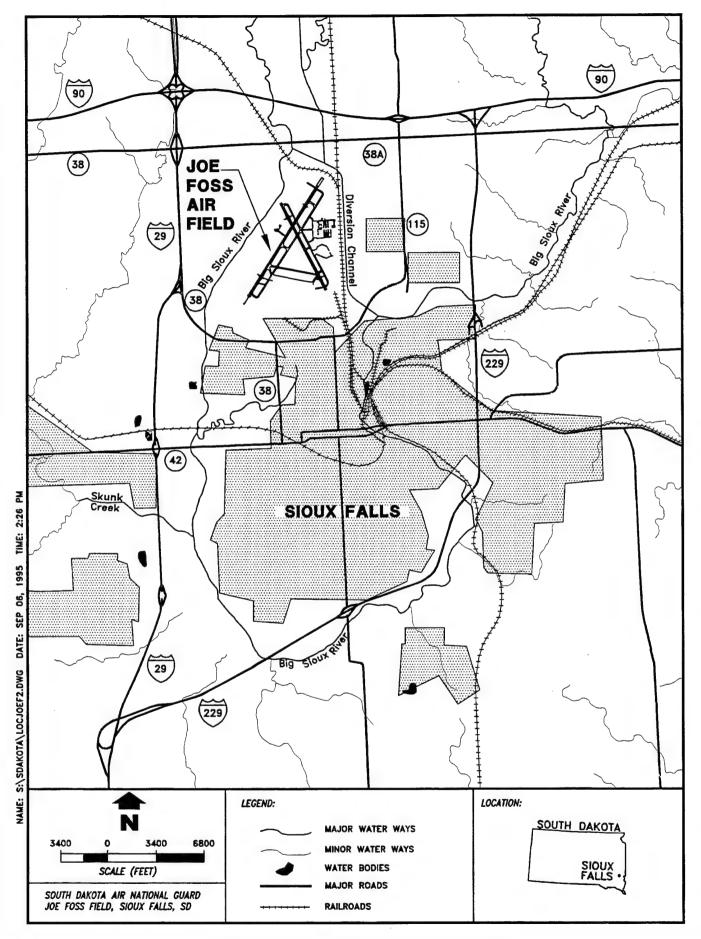

Figure 1-1. Location of Joe Foss Airfield

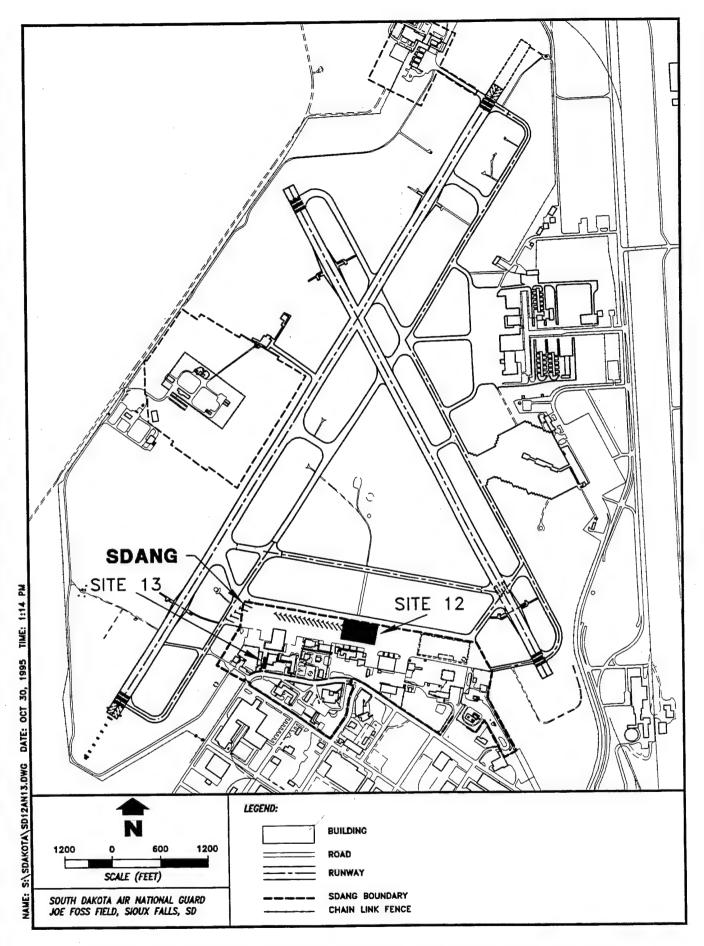

Figure 1-2. Location of SDANG within Joe Foss Airfield and Sites 1 and 3

A Preliminary Assessment (PA) of SDANG was conducted by the Hazardous Materials Technical Center (HMTC) in 1986 to identify areas that required further study. Previous investigations of SDANG have included site investigations of areas southeast and northwest of Sites 12 and 13; Remedial Investigations (RIs) of Site 1 - Underground Fuel Storage Area and Site 3 - Base Fire Training Area (Figure 1-2), resulting in the installation of an extraction and treatment system (ETS) to remove volatile organic compounds (VOCs) at Site 1 and soil at Site 3; and underground storage tank (UST) removal at Sites 8, 9, 10, and 11 (Figure 1-3).

Soil contamination at Site 12 - Ramp Area was first observed in 1993 during routine ramp repair. Soil contamination at Site 13 - MVMF was first observed in 1994 when posts were being installed around the fuel dispensing island. Observations made when the contamination was discovered were odors indicative of petroleum fuel.

#### 1.2 PURPOSE AND SCOPE

The objective of the SI conducted at Sites 12 and 13 was to confirm the presence or absence of petroleum and/or solvent contamination in subsurface soils and groundwater at the two sites. This report presents the approach to the SI field investigation, describes the field screening and laboratory analytical results, and makes recommendations for future action at the sites.

The scope of work for the SI included a soil organic vapor (SOV) survey, subsurface soil and groundwater sampling using a hydraulic probe, installation of piezometers and monitoring wells, and two rounds of monitoring well sampling. All work was conducted in accordance with Federal, state, and local regulations, and followed site-specific sampling and health and safety protocols, as specified in the SI Work Plan (SAIC 1995). Laboratory chemical analyses were conducted in accordance with project quality assurance/quality control (QA/QC) requirements as presented in the Quality Assurance Project Plan (QAPP) (Appendix A of the SI Work Plan).

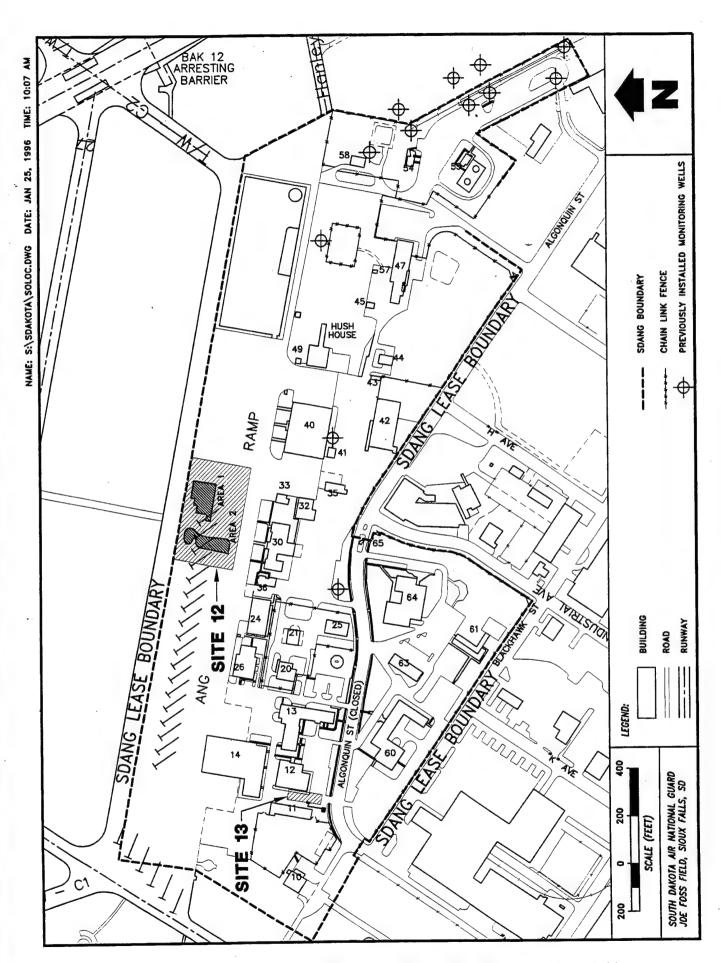

Figure 1-3. Location of Sites 12 and 13, and Sites 8, 9, 10, and 11

The report is organized into the following sections. Section 2 describes the location, organization, and history of the SDANG facility. This includes the results of the PA conducted at SDANG (HMTC 1986) as well as information concerning specific activities associated with Sites 12 and 13. Section 3 describes the geologic, hydrogeologic, climatic, and ecologic setting of the study area, including specific information obtained during the SI at Sites 12 and 13. Section 4 discusses the approach and procedures used during the SI field investigation, and includes information on the SOV survey, hydraulic probe sampling, and piezometer and well installation. Section 5 evaluates the field screening and laboratory analytical results for Sites 12 and 13, and summarizes the extent of soil and groundwater contamination. In Section 6, conclusions are made for each site, and recommendations for future action at each site are outlined in Section 7 based on these conclusions. The data generated for the SI are presented in the appendices, including boring logs and construction diagrams for the monitoring wells installed. The *Data Requirements for Federal Facility Docket Sites*, which enables the U.S. Environmental Protection Agency (EPA) to perform hazard ranking, is included in Appendix G.

#### 1.3 METHODOLOGY

The following methodology was adopted to minimize the number of soil borings and monitoring wells to be installed in order to confirm the presence or absence of contamination in soil and groundwater at Sites 12 and 13. Section 4 contains specific information on investigative methods and equipment.

An SOV survey was conducted at both Sites 12 and 13. The SOV survey was used to estimate the extent of subsurface soil contamination, and to determine optimum locations for hydraulic probe sampling and monitoring wells. During the SOV survey, soils were screened for VOCs and total petroleum hydrocarbons (TPH). During the hydraulic probe survey of Site 12, groundwater screening for VOCs and TPH was conducted to characterize the groundwater quality beneath the site.

Groundwater samples were collected using the hydraulic probe at Sites 12 and 13, and from six monitoring wells. Groundwater sampling locations, including piezometer and monitoring well locations, were chosen by the ANGRC hydrogeologist and SAIC, with

concurrence from the South Dakota Department of Environment and Natural Resources (DENR). Monitoring well samples were collected to characterize groundwater quality at Sites 12 and 13. These samples were analyzed for TPH and benzene, toluene, ethylbenzene, and xylenes (BTEX); at Site 13, samples also were analyzed for eight organic solvents (vinyl chloride, chloroform, 1,1,1-trichloroethane, trichloroethene, 1,2-dichloroethene, tetrachloroethene, and carbon tetrachloride).

Subsurface soil samples were collected using the hydraulic probe to characterize soil contamination. Subsurface soil samples from depths of 0 to 9 feet were analyzed for TPH and BTEX at Site 12; at Site 13, samples also were analyzed for solvents. Subsurface soil samples were collected during monitoring well installation to further characterize the geology of the subsurface materials. One sample was collected from each monitoring well boring for laboratory geotechnical testing (maximum depth of 15 feet).

THIS PAGE WAS INTENTIONALLY LEFT BLANK

#### 2. INSTALLATION DESCRIPTION

This section describes the location of the South Dakota Air National Guard (SDANG), including the locations of Site 12 - Ramp Area and Site 13 - Motor Vehicle Maintenance Facility (MVMF). The organization and history of SDANG is summarized, and individual histories of Sites 12 and 13 are provided.

#### 2.1 LOCATION

Joe Foss Field is the municipal airport for Sioux Falls, South Dakota. The airfield is located within the city limits of Sioux Falls and is 2 miles north of the downtown area (Figure 1-1). The SDANG facilities occupy 166 acres in the southern portion of Joe Foss Field and contain hangers for aircraft parking and repairs, and buildings for administration and vehicle maintenance (Figure 1-2).

Both Sites 12 and 13 are located within the SDANG facilities. Site 12 - Ramp Area is located north of Building 30 and in the north-central portion of SDANG. Site 13 - MVMF consists of Building 11 and a fuel dispensing station located east of Building 11 in the western portion of SDANG (Figure 1-3).

#### 2.2 ORGANIZATION AND HISTORY

The 114th Fighter Wing of SDANG shares the airfield with civilian aviation. The property has been leased by the Air National Guard (ANG) from the city of Sioux Falls since 1946. The municipal airport at Sioux Falls was built in 1935 by the Works Progress Administration. On July 6, 1942, the U.S. Army opened the Sioux Falls Radio Technical School at the airport on land acquired from the city of Sioux Falls. The training school officially closed on May 31, 1945, and became the Sioux Falls Army Airfield on June 1, 1945. On December 31, 1945, the Sioux Falls Army Airfield was deactivated and the property was reverted to the city of Sioux Falls. SDANG was established at the Sioux Falls Municipal Airport on September 20, 1946.

In support of its primary mission of providing air combat preparedness, the Base has stored and used various types of hazardous materials, such as fuel and oil, during its history. Although some historical operations at SDANG have resulted in the storage and use of hazardous materials, not all of these operations relate to Installation Restoration Program (IRP) sites. Table 2-1 summarizes the operations conducted at the Base, and the hazardous substance activities associated with these operations.

#### 2.2.1 Previous Activities

A Preliminary Assessment (PA) was conducted at SDANG by the Hazardous Materials Technical Center (HMTC) in 1986. The PA identified the following two sites for further study: Site 1 - Underground Fuel Storage Area and Site 3 - Base Fire Training Area. Remedial Investigations (RIs) of Sites 1 and 3 were completed by Science Applications International Corporation (SAIC) in July 1989 (SAIC 1990). Both investigations resulted in remedial actions. At Site 1, a treatment system was installed. Soils were excavated and transported to a landfill at both Sites 1 and 3. In November 1993, the operation of the treatment system at Site 1 was discontinued because the influent to the treatment system met the National Pollutant Discharge Elimination System (NPDES) criteria for total petroleum hydrocarbons (TPH) and benzene, toluene, ethylbenzene, and xylenes (BTEX). The South Dakota Department of Environment and Natural Resources (DENR) requires no further soil excavation at Sites 1 and 3, and no additional groundwater monitoring at Site 3 (DENR 1993).

Because of the geographic distance of Sites 1 and 3 from Sites 12 and 13, and the closure of the sites by the South Dakota DENR, a detailed review of the remedial activities and the supporting data from these activities is not included in this Site Investigation (SI) report.

Underground storage tanks (USTs) and any associated contaminated soils have been removed from Sites 8, 9, 10, and 11 (Figure 1-3).

#### 2.2.2 Background and Operational History of Site 12

Site 12 - Ramp Area is used for refueling, taxiing, and parking aircraft. Site 12 is part of a larger aircraft parking apron and taxiway at SDANG. SDANG initiated a ramp repair

Table 2-1. History of Base Operations South Dakota Air National Guard, Sioux Falls, South Dakota

Period	Type of Operations	Mission/ Weapon Systems	Hazardous Substance Activity

Source: SAIC 1995

project in 1993, consisting of removing selected areas of the existing concrete parking apron and taxiway, preparing the subgrade, installing an underdrain system, and replacing the concrete pavement. Following removal of the existing concrete pavement, construction personnel noted petroleum odors in two areas (designated Areas 1 and 2). The location of these areas in relation to existing structures is illustrated in Figure 2-1. Area 1 is located north of Building 30 and Area 2 is located west of Area 1. Soil contamination was observed along the expansion joints using a photoionization detector (PID). Soils were excavated to a depth of 8 feet below land surface (BLS) at Area 1 and 3 feet BLS at Area 2. The excavation depth was determined based on field screening of soil samples for organic vapors using two PIDs. At both Areas 1 and 2, the soil contamination was localized and varied with depth (e.g., Area 2 PID data indicated contamination at ½ foot depth (375 ppm) and no contamination at depths of 1, 2, and 3 feet BLS). At Area 1, organic vapor concentrations at a depth of 8 feet BLS ranged from nondetect (ND) to a maximum of 353 ppm (Geotek 1993). Approximately 1,524 tons of petroleum-contaminated soils were removed and transported to the Runge Landfill in Sioux Falls, South Dakota.

#### 2.2.3 Background and Operational History of Site 13

Site 13 - MVMF was constructed in 1976 and consists of an Automotive Maintenance Shop (Building 11) and a fuel dispensing station located east of Building 11, as shown in Figure 2-2. The facility consists of three 2,000-gallon above-ground fuel storage tanks, which are located south of Building 11. The buried fuel lines from the tanks to the dispensing pumps were tested for leaks in May 1993 and August 1994. On both occasions, the lines passed the leak detection test (SAIC 1995). The area around the fuel dispensing island is paved with asphalt. Soil contamination was first observed when concrete posts were being installed around the fuel dispensing island in July 1994.

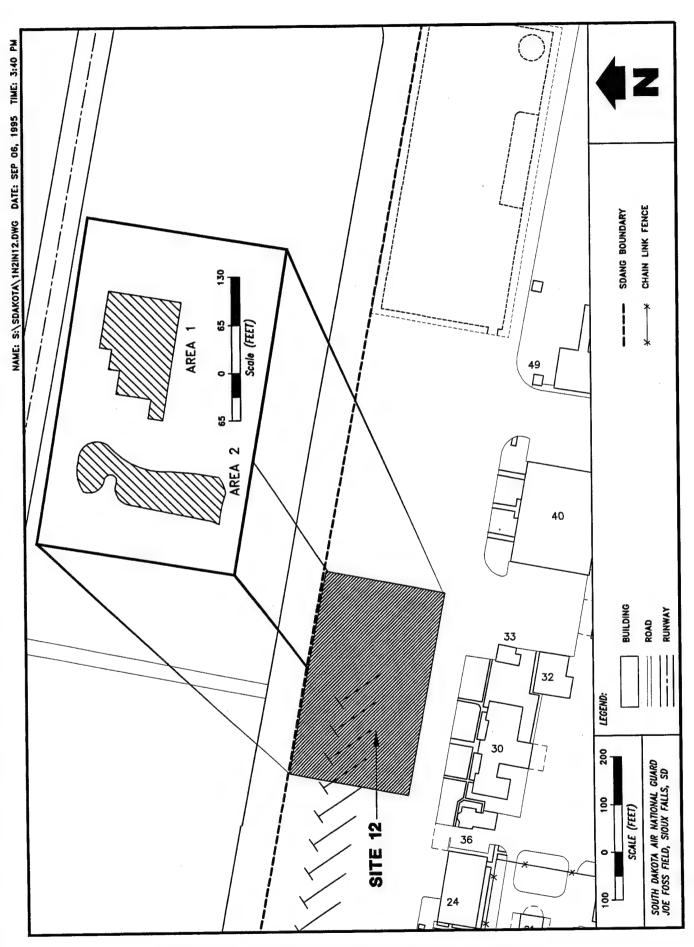

Figure 2-1. Location of Areas 1 and 2 within Site 12

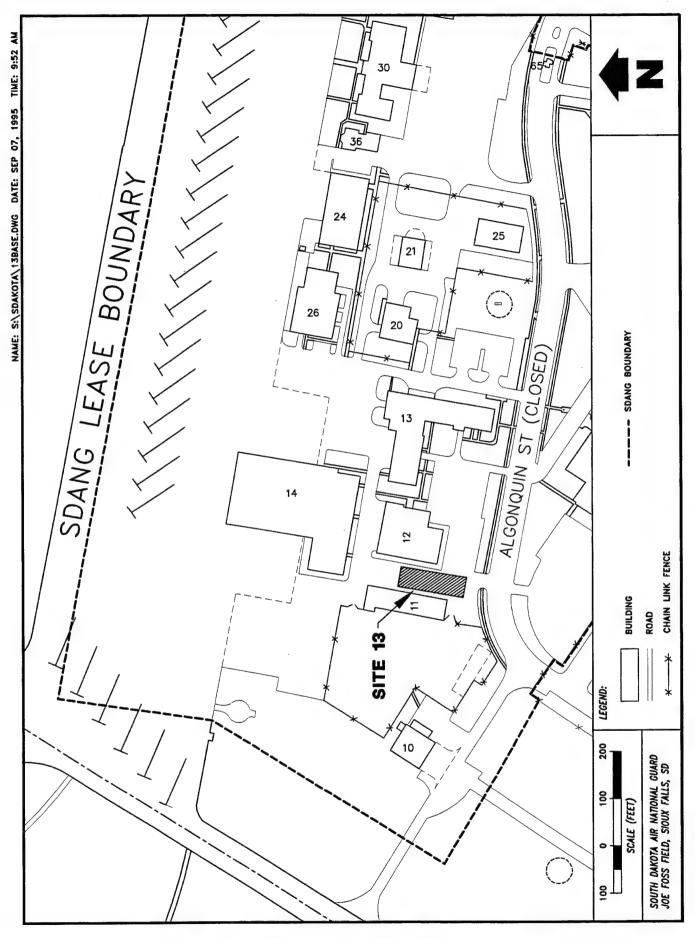

Figure 2-2. Location of Site 13

### 3. ENVIRONMENTAL SETTING

This section summarizes the geographical setting, regional and site geology, hydrology, climate, and critical habitats/endangered species for the South Dakota Air National Guard (SDANG). Sioux Falls is located in the Big Sioux River Valley in southeastern South Dakota. The surrounding terrain is composed of gently rolling hills, typical of the glaciated midwestern United States.

SDANG lies at the extreme southern edge of the Coteau des Prairies (Prairie Hills). This feature is a highland plateau in the western part of the Central Lowland Province, between the Minnesota River lowland to the east and the James River lowland to the west. The Big Sioux River, which runs adjacent to SDANG, is the only large stream that drains the Coteau des Prairies (Koch 1982).

SDANG lies entirely within the floodplain of the Big Sioux River, which has a flooding recurrence interval of 2.3 years (Jorgensen and Ackroyd 1973). Consequently, the associated topography of the SDANG area has little or no relief within a 1-mile radius of the site, as Figure 3-1 shows. The floodplain lowland is approximately 3 miles wide in the area of the airfield, which is nearly centered upon the floodplain. The Big Sioux River and the Diversion Channel have low gradients near the airfield.

### 3.1 METEOROLOGY

Climatic data for Sioux Falls are based on National Oceanic and Atmospheric Administration (NOAA) records from 1958 to 1987. The mean annual temperature in Sioux Falls is 46.1°F. Annual precipitation averages 25.18 inches. The wettest month is June, with an average precipitation of 4.14 inches. January is the driest month, with an average precipitation of 0.60 inches. Annual snowfall averages 39.7 inches. Net precipitation for the area is negative 9.63 inches per year, when calculated according to the method given in the Federal Register (HMTC 1986). Rainfall intensity based on a 1-year, 24-hour rainfall is 4.59 inches (HMTC 1986).

THIS PAGE WAS INTENTIONALLY LEFT BLANK

#### 3.2 GEOLOGY

### 3.2.1 Regional Geology

The geology of the Sioux Falls area is dominated by the effects of continental glaciation. The study area is within the Coteau des Prairies, a highland plateau. Figure 3-2 shows a generalized conceptual representation of the geology of this area (USDA 1964). This high plateau is an expression of the Sioux Uplift, a bedrock high that occurs within the area. The bedrock high deflected the southward advancing ice sheets to the east and the west and protected the highland area from glacial erosion. The Coteau des Prairies is flanked to the east and west by the moraines of these deflected ice sheets. Glacial outwash was deposited by streams of glacial meltwater originating from the continental ice sheets, on either side of the Coteau des Prairies, during periods of glacial retreat. The meltwater from these surrounding ice sheets was directed onto the Coteau des Prairies and into the Big Sioux River, which was a much larger braided river at the time.

The geology in the region consists of crystalline bedrock overlain by as much as 200 feet of glacial deposits. Within the Big Sioux River valley there is a thin (generally less than 15 feet), discontinuous mantle of alluvial sediments overlying the glacial deposits (Jorgensen and Ackroyd 1973).

In the Coteau des Prairies, bedrock consists of the Sioux Quartzite of Precambrian Age, thought to be more than 4,000 feet thick. The quartzite forms bedrock highs both in the Sioux Falls area and to the north near the town of Dell Rapids, where it forms rapids and waterfalls. In outcrop, this fine-grained formation exhibits relict bedding features, is extremely hard and fractured, and is pink (Jorgensen and Ackroyd 1973).

Approximately 200 feet of glacial sediment cover the quartzite over most of the region, with the exception of areas near bedrock highs, where sediments overlying the bedrock gradually thin and "pinch out." The sediment consists primarily of glacial till and glacial outwash. The glacial till is characterized by unstratified, unsorted masses of glacial debris, ranging in size from fine clayey material to large boulders. The till is approximately 200 feet thick in some parts of the Coteau des Prairies, but is generally thinner in the Big Sioux River valley, where

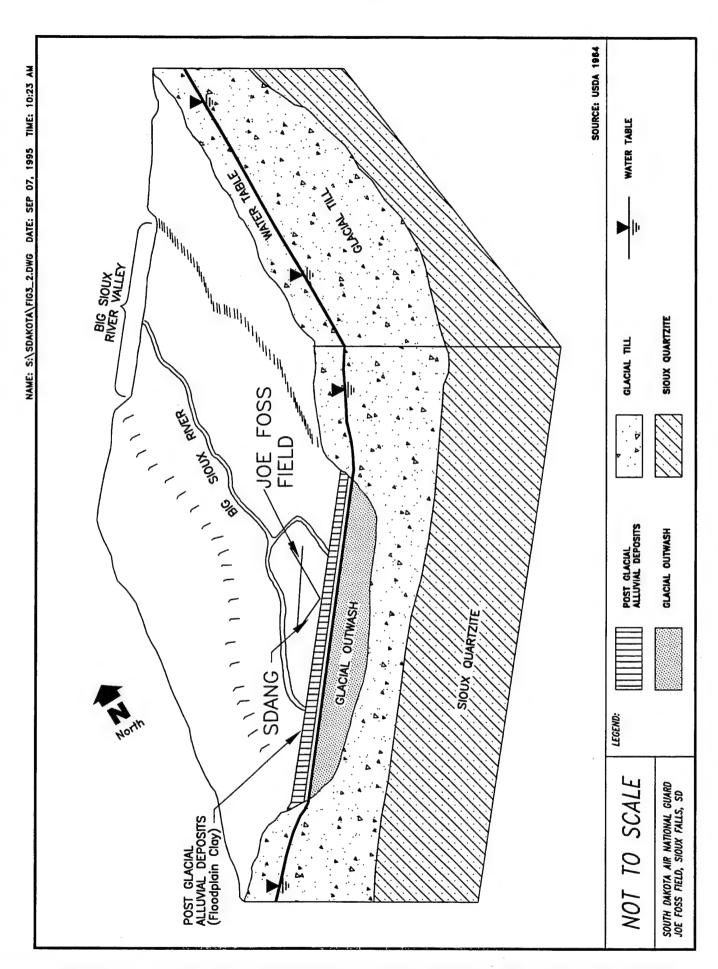

Figure 3-2. Generalized Hydrogeologic Conceptual Model of the Coteau des Prairies

it has been eroded by the scouring of the river. The till is very thin or nonexistent in the localized bedrock high areas in the Sioux Falls area.

Restricted laterally to the river valley and to the north and south by Sioux Quartzite outcrops, at least 50 feet of coarse-grained glacial sediment has been deposited upon the till. This glacial outwash consists of stratified coarse sand and gravel along with trace amounts of silt and clay.

A variably thick (0- to 20-foot) mantle of post-glacial alluvial deposits overlies the sediment within the river valley. Post-glacial alluvial deposits were formed by re-deposition of glacially derived sediments by the Big Sioux River. The deposits consist of very fine-grained floodplain deposits with some slightly coarser-grained river channel deposits. Because of their thinness and surface location, the floodplain deposits have been disturbed by construction activities throughout the valley.

# 3.2.2 Site Geology

Soil sampling associated with drilling operations during the Site Investigation (SI) provides details on the subsurface geology at SDANG. Additional information was obtained from soils data collected during the 1986 Remedial Investigation (RI) at Site 1 - Underground Fuel Storage Area and Site 3 - Base Fire Training Area (SAIC 1990). Sediments encountered included post-glacial alluvial deposits (floodplain clay), glacial outwash, and glacial till (SAIC 1990). Soil boring logs from the SDANG SI field program are presented in Appendices B, C, and D.

A surface layer of post-glacial alluvial deposits was encountered in all soil borings and monitoring wells at SDANG. The layer was laterally continuous throughout the site, with the exception of Site 1 - Underground Fuel Storage Area and Site 9 - Underground Storage Tank. At these sites, past construction activities have disturbed or eliminated this layer. In general, this 6- to 15-foot thick deposit consists of dark gray, clayey silt with traces of fine sand. However, in the area of Site 12 - Ramp Area and Site 13 - Motor Vehicle Maintenance Facility

(MVMF), this layer consists of very dark brown to black, very fine, highly plastic clay, which grades into a dark gray to brown, clayey silt with traces of fine sand.

Glacial outwash was encountered underlying the surface alluvial deposits. The deposits ranged from 20 to approximately 25 feet thick at Site 1. Samples generally were composed of gray to dark olive brown, sandy gravels with traces of silt and clay. Glacial till was found beneath the outwash at Site 1. The outwash/till contact was located at a depth of approximately 30 to 35 feet. The thickness of this till unit is approximately 100 to 130 feet in the vicinity of SDANG (Koch 1982). However, during the SI, the base of the till was not penetrated.

The character of the post-glacial alluvial deposits determines the soil types found at the sites. Figure 3-3 shows the soil types present in the immediate area of SDANG. The majority of these soil types are in the Luton-Dimmick association. These soils consist of fine-textured to moderately fine-textured floodplain soils. The soil type underlying both Sites 12 and 13 is the Luton, which is the finest grained of the association. In addition, the Rauville and Dimmick soils are close to each site; these soil types are slightly coarser grained and are associated with river channel deposits (USDA 1964).

#### 3.3 REGIONAL AND LOCAL HYDROLOGY

# 3.3.1 Regional Subsurface Hydrology

The primary aquifer in the Sioux Falls area, the Big Sioux Aquifer, constitutes approximately 36 square miles within the saturated portions of the gravelly sand glacial outwash deposits, as shown in Figure 3-4. This figure also illustrates the approximate boundaries of the aquifer. The water table aquifer is generally bounded underneath and to the east and west by glacial till and to the north and south by the bedrock highs of the Sioux Quartzite. These materials form low permeability boundaries to the aquifer. Regionally, the aquifer ranges in thickness from 0 feet where the sediments pinch out along the valley flanks and Sioux Quartzite outcrops, to as much as 50 feet within the south-central portions of the valley.

Recharge of the aquifer is primarily by precipitation infiltration and seepage from the Big Sioux River. Of the precipitation that fell within the drainage area of the Big Sioux River

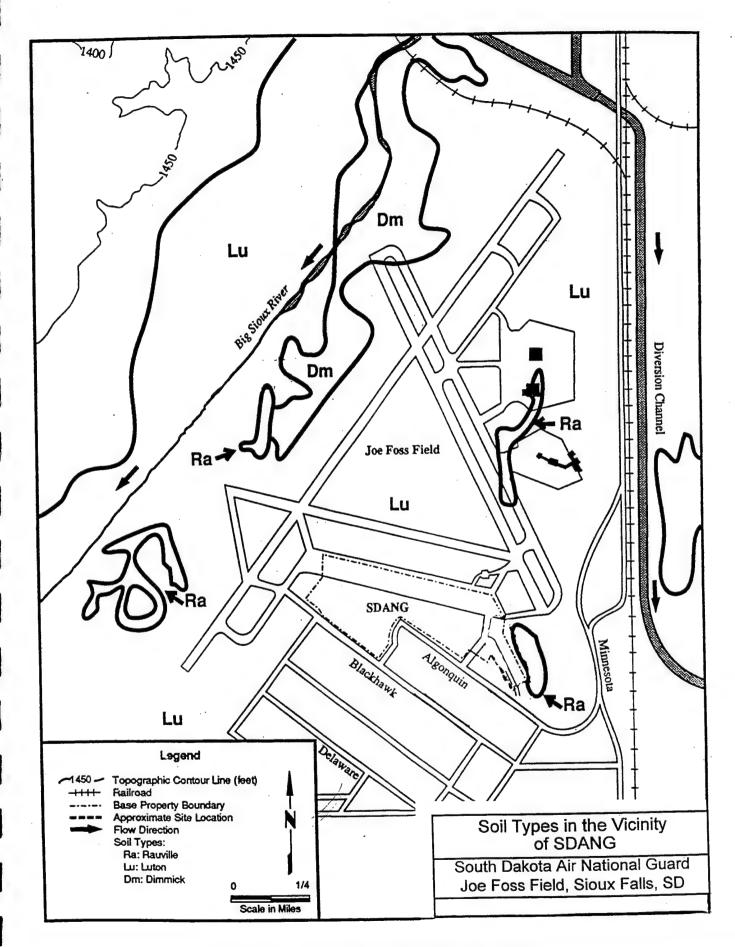

Figure 3-3. Soil Types of SDANG and Vicinity

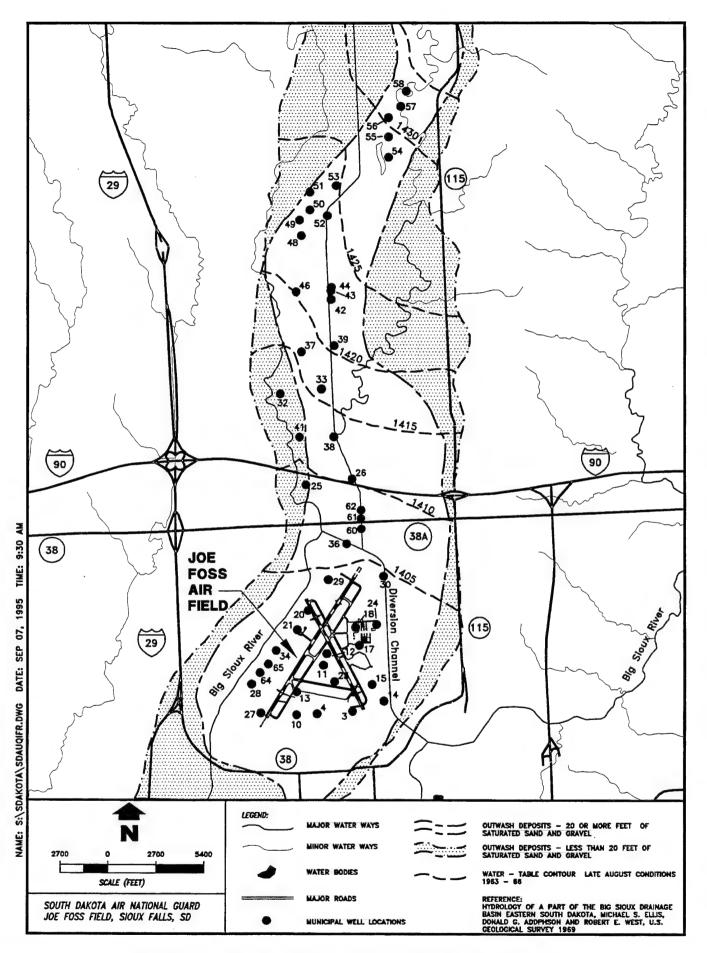

Figure 3-4. The Big Sioux Aquifer at SDANG and Vicinity

between 1970 and 1979, an estimated 90.5 percent was returned to the atmosphere through evapotranspiration, 1.5 percent was contributed to the surface water runoff, and 8 percent was added to aquifer storage (Koch 1982). Recharge by river seepage occurs primarily in the southern third of the aquifer where seepage is induced by the pumping of the city of Sioux Falls municipal well field. During periods of low stream flow, as much as 95 percent of the stream flow may infiltrate into the aquifer in this area (Koch 1982). Stream bed infiltration rates have been measured ranging from 4 to 7.4 gallons per day per foot (gal/day/ft) and vary according to scouring of the stream bed, the influence of dams, dredging activities, and stream levels (Jorgensen and Ackroyd 1973).

Discharge of the aquifer occurs through evapotranspiration and seepage into the Big Sioux River and by groundwater pumpage. Discharge by seepage from the aquifer into the river occurs primarily in the northern two-thirds of the aquifer. Groundwater pumpage occurs primarily in the southern third of the aquifer by the city of Sioux Falls municipal well field. Approximately 3.2 billion gallons were extracted from the aquifer in 1993.

The following information represents average trends and that the hydrologic system is dynamic, fluctuating seasonally and yearly, depending on the relative strengths of the components of aquifer recharge and discharge. Groundwater table depths vary from 0 to 20 feet below land surface (BLS). Water table elevations range from 1,400 to 1,470 feet above mean sea level (msl) in the southern and northern portions of the aquifer, respectively. Yearly groundwater level fluctuation averages 4.2 feet, depending on pumping and precipitation amounts (Koch 1982). Groundwater levels tend to rise in the spring and early summer when precipitation (snowmelt and rainfall) infiltration is highest. Levels are lower from mid-summer to late fall when precipitation is low and groundwater pumpage is at a maximum. Significant changes in the water levels in the aquifer depend upon recharge and withdrawal rates. During the SI field program, the water table was present at 7 to 9 feet BLS. As a part of their water level monitoring program, the city of Sioux Falls has collected and recorded water level measurements in as many as 71 monitoring wells completed in the Big Sioux Aquifer since 1979. Currently, the water levels in 53 monitoring wells are measured monthly and an additional 10 monitoring wells are monitored 2 to 4 times a year.

In the northern two-thirds of the aquifer, groundwater flow is generally north to south, with a component of flow toward the river, where groundwater discharges. In the southern one-third of the aquifer, groundwater flow directions are influenced by pumping at the municipal well field. Generally, flow is directed radially inward toward the central portion of the valley.

Hydraulic conductivity (K) values range from 1,500 to 6,500 gal/day/ft ( $10^{-2}$  to  $10^{-1}$  cm/sec) (Koch 1982). Hydraulic conductivity values obtained by the city of Sioux Falls for short-term pumping tests of 39 municipal wells ranged between 5.54 x  $10^{-1}$  cm/sec and  $2.0 \times 10^{-2}$  cm/sec (HDR 1990).

The primary use of groundwater in the southern one-third of the Big Sioux Aquifer is the municipal water supply for the city of Sioux Falls. The production wells are located in a well field that covers the southern one-third of the aquifer. The majority of these wells are located adjacent to the Big Sioux River to take advantage of induced recharge effects. Figure 3-4 and Table 3-1 show the locations of the municipal wells and 1994 pumpage for the municipal water supply, respectively. In 1994, total pumpage from these groundwater wells exceeded 3.2 billion gallons. The well field is augmented by two surface water intakes within the Diversion Channel, which supplied 2 billion gallons in 1993. Municipal wells 3, 4, 10, 13, 15, and 23, located near SDANG, are only pumped periodically by the city for preventive maintenance and are not currently in use for water supply. Relatively small amounts of groundwater also are used for water supply in small communities to the north and for irrigation purposes throughout the valley.

### 3.3.2 Site Hydrology

The saturated outwash deposits comprise the Big Sioux Aquifer in the study area. Characteristics of this aquifer are summarized in Table 3-2. Figure 3-5 shows the hydrograph of the water level measured in 1993 in municipal wells 4, 10, 14, and 15 located near SDANG. The static water level fluctuations agree with the seasonal variations of higher levels in the summer and decreasing during the fall and winter. The static water levels during the SI were higher than those observed during the RI conducted at SDANG in 1988 and 1989 due to higher than normal precipitation.

# **Groundwater Elevations - 1994**

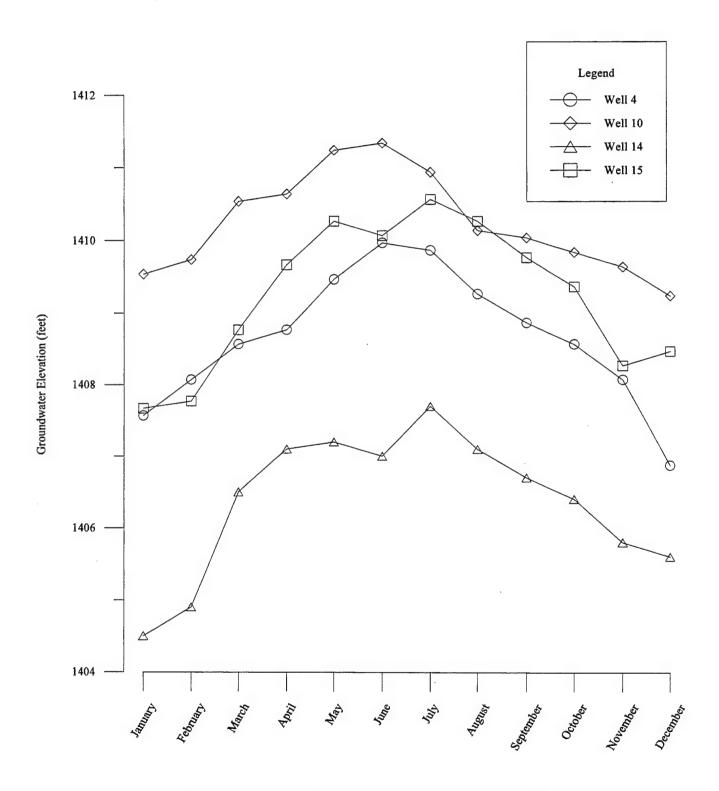

Figure 3-5. Hydrograph of Selected Municipal Wells

During piezometer and monitoring well installations within Sites 12 and 13, static water levels ranged from approximately 6 to 7 feet BLS, as shown in Figure 3-6. Flow direction determined using data from the three newly installed piezometers at Site 12, was to the southwest.

# 3.4 CRITICAL HABITATS/ENDANGERED OR THREATENED SPECIES

#### 3.4.1 Wetlands

The U.S. Fish and Wildlife Service (USFWS) recognizes wetlands as vital resources for migratory waterfowl; therefore, wetlands are considered under USFWS's "no net loss of wetlands" policy. As part of the Federal Government's program to preserve and enhance the Nation's wetlands, the National Wetlands Inventory (NWI) project has developed maps of wetland types.

The NWI map of designated wetlands in the area of SDANG is presented in Figure 3-7. Table 3-3 describes the abbreviations used in the figure. Most of the wetlands near SDANG are temporary. Several of these small wetland areas are located near the Base Fire Training Area (Site 3). However, no wetlands have been identified in or around Sites 12 and 13.

Table 3-3. Descriptions of Wetland Designations for Sioux Falls, South Dakota Area

Wetland Designation	Description
PEMA	Palustrine, emergent, temporarily flooded
PEMAx	Palustrine, emergent, temporarily flooded, artificially excavated
R2UBGx	Lower perennial riverine, unconsolidated bottom, intermittently exposed, excavated

Source: U.S. Department of the Interior, Fish and Wildlife Service, South Dakota State Office (1989)

# 3.4.2 Endangered and Threatened Species

Information on rare and threatened species that may be found within or near the project area was obtained from the U.S. Department of the Interior (DOI) and the South Dakota Department of Game, Fish, and Parks. Table 3-4 lists these species and their environment of

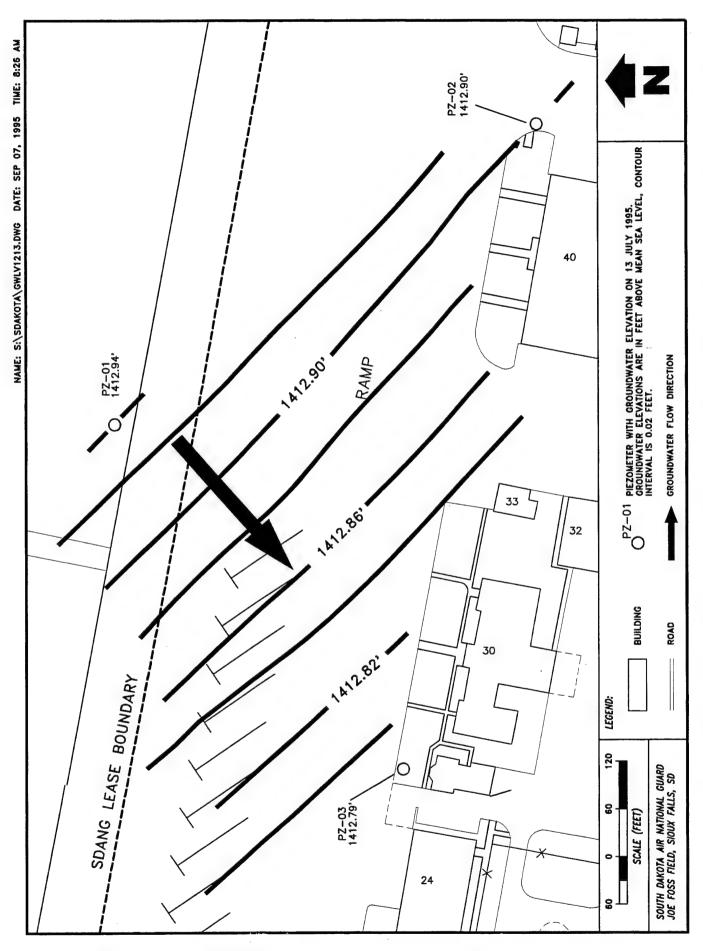

Figure 3-6. Groundwater Levels in Piezometers at Site 12 on 13 July 1995

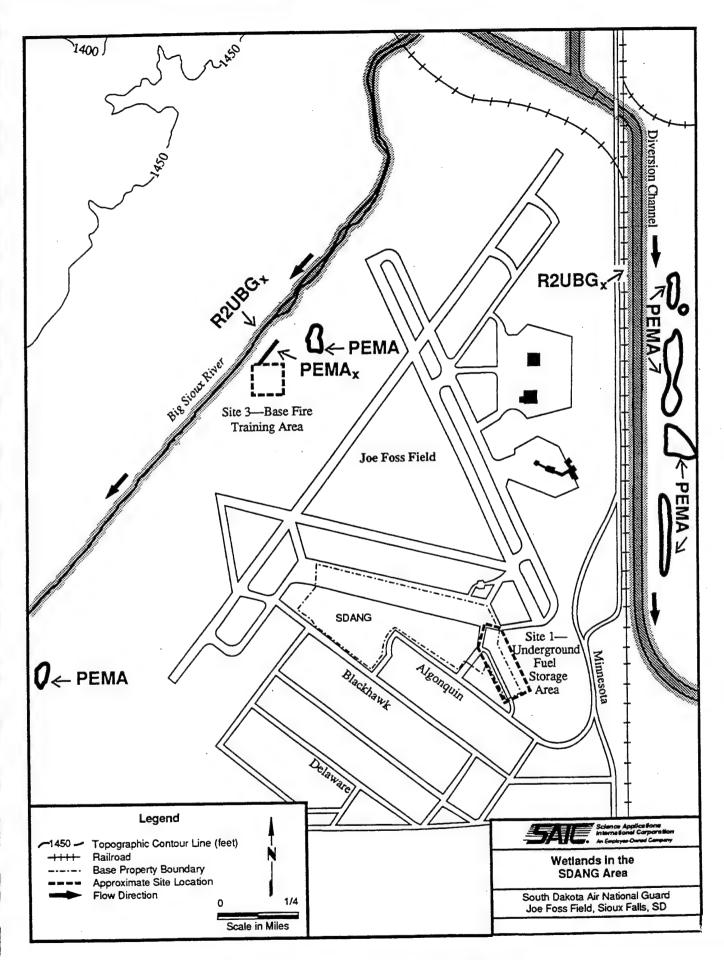

Figure 3-7. Wetlands in the SDANG Area

probable occurrence. The species consist of two prairie plants, an amphibian, and several species of migratory birds. There is no reason to expect that any of these bird species would be attracted to the site, since no critical habitats exist for these species in the vicinity of the site.

Table 3-4. Endangered Species Summary for the Greater Sioux Falls, South Dakota Area

Rare and Unique Species	Expected Occurrence
Bush Clover Lespedeza Capitata	Rare in South Dakota; occurs in native, tallgrass prairies
Compass Plant Silphium Laciniatum	Rare in South Dakota; occurs in native, tallgrass prairies
Blanding's Turtle  Emydoidea Blandingii	State-threatened species; prefers calm, shallow waters, rich, aquatic vegetation, and sandy uplands for nesting
Federally Endangered Species	
Bald Eagle Haliaeetus Leucocephalus	Winters along the Missouri River
Peregrine Falcon Falco Peregrinus	Regarded as a migrant; usually associated with wetlands and open areas
Eskimo Curlew Numenius Borealis	A species associated with native prairies

#### 4. FIELD PROGRAM

This section summarizes the field activities conducted at Site 12 - Ramp Area and Site 13 - Motor Vehicle Maintenance Facility (MVMF) at the South Dakota Air National Guard (SDANG) as part of the Site Investigation (SI). The rationale and methods used for the geologic and hydrogeologic investigations, including field screening activities and the disposal of project-derived wastes, are discussed. An explanation of deviations of the field activities from those outlined in the approved SI Work Plan (SAIC 1995) is included. The results of the field activities are presented in Section 5.

### 4.1 GENERAL APPROACH

Field investigation methods used during the SI included a soil organic vapor (SOV or "soil gas") survey, subsurface soil and groundwater sampling using a hydraulic probe, and installation of piezometers and monitoring wells. Field screening activities were conducted to identify potential contaminant source areas. Local groundwater flow direction was estimated using water level elevations from piezometers installed during the SI. The screening results and groundwater flow direction were evaluated to determine the optimum locations of the monitoring wells. The following approach was used during the SI:

- An SOV survey was conducted at both sites to define potential contaminant source areas. Soil gas samples were collected at 2-foot intervals down to groundwater and screened onsite for total petroleum hydrocarbons (TPH), and benzene, toluene, ethylbenzene, and xylenes (BTEX). At Site 13, soil gas samples also were screened for eight common solvents, including vinyl chloride, chloroform, 1,1,1-trichloroethane, trichloroethene, 1,2-dichloroethene, tetrachloroethene, and carbon tetrachloride.
- At Site 13, 20 groundwater samples were collected using a hydraulic probe and screened in the onsite laboratory for TPH, BTEX, and eight common solvents.
- Soil samples were collected using a hydraulic probe. Two soil samples from each sampling location were selected for offsite laboratory analyses. Samples were chosen based on the screening results from each 2-foot interval. Soils were analyzed for TPH and BTEX; at Site 13, soil samples also were analyzed for eight common solvents.
- At Site 12, five groundwater samples were collected (one from each of the five soil sampling locations). These samples were analyzed at the offsite laboratory for TPH and BTEX.

- Three 2-inch diameter piezometers were installed to a depth of 15 feet below land surface (BLS). Groundwater flow direction was calculated using water level measurements from the piezometers.
- Five 4-inch diameter monitoring wells were installed at Site 12 to 15 feet BLS.
- One 2-inch diameter monitoring well was installed at Site 13 to 20 feet BLS. Groundwater samples were analyzed for TPH, BTEX, and eight common solvents.
- One sample was collected from each monitoring well boring for laboratory geotechnical testing (maximum depth of 15 feet).

#### 4.2 FIELD ACTIVITIES

Field activities conducted as part of the SI at SDANG included an SOV survey, sampling soil and water using a hydraulic probe, onsite screening of samples, piezometer installation, and monitoring well installation and sampling. The following subsections present the methods and procedures for these activities. All field activities were documented in the field logbook (Appendix L). Results of all SI field activities are presented in Section 5.

# 4.2.1 Soil Organic Vapor Survey

An SOV survey was conducted at both sites to identify potential contaminant source areas. An electric hammer was used to core a 2-inch diameter hole through the concrete where necessary to initiate sampling activity. Prior to sampling, the SOV sampling equipment was purged with ambient air filtered through an organic vapor filter cartridge. Interconnected 3-foot lengths of 1-inch diameter steel pipe were then advanced to the appropriate sampling depth using a truck-mounted hydraulic probe. The bottom of the pipe was opened and a small diameter stainless steel probe attached to a length of Teflon® tubing was lowered through the steel casing to the bottom of the hole and screwed into a fitting at the bottom end of the pipe. The attachment to this fitting ensures that the sample comes from the soil at that interval and not from the inside of the steel pipe. In situ soil gas was withdrawn through the probe and used to purge the sampling equipment. A second sample of soil gas was withdrawn through the probe into a pre-evacuated, self sealing, U.S. Environmental Protection Agency (EPA)-approved clean glass vial at a pressure of two atmospheres. The glass vials were then taken to the onsite laboratory for analysis by gas chromatography (GC).

SOV samples were taken at 2-foot intervals, starting at 2 feet BLS, until groundwater was encountered. Samples were started at a depth of 2 feet BLS because of the thickness of the concrete at Site 12 and the asphalt at Site 13. Soil gas samples were collected to a maximum depth of 8 feet BLS. SOV survey results are presented in Appendix A.

### 4.2.2 Groundwater Field Screening

Groundwater samples at Site 12 were collected for offsite screening of BTEX and TPH (see Section 4.2.4). At Site 13, 20 groundwater samples were collected and screened onsite for BTEX, TPH, and eight common solvents. The truck-mounted hydraulic probe was used to advance interconnected 3-foot lengths of 1.25-inch diameter steel pipe into groundwater. The steel pipe was then replaced with a slotted 0.5-inch diameter polyvinyl chloride (PVC) temporary well point. Groundwater samples were collected with a stainless steel mini-bailer. Two to three 40-mL EPA-clean glass volatile organic analysis (VOA) vials were filled for each sample, depending on the productivity of the well. Samples were analyzed at the onsite laboratory.

# 4.2.3 Soil Field Screening

Soil samples were collected at Sites 12 and 13 using the hydraulic probe. The sampling team collected samples at 2-foot intervals until groundwater was encountered, according to direction from the Air National Guard Readiness Center (ANG) (see Section 4.6). Soil samples from each sampling interval were screened at the onsite laboratory (TARGET) using the GC. Using data from the screening analyses, two samples were selected from each sampling point, for analysis by the offsite laboratory (Maxim Technologies, Inc., formerly Huntington Engineering and Environmental, Inc.).

Soil samples were collected by hydraulically driving a 1.25-inch-diameter piston-type sampler to the top of the desired sample interval. The piston within the sampler was then removed and the sample corer was advanced to collect a 2-foot core. The soil core was contained in a non-reactive plastic liner. The liner was opened and screened for volatile organic compounds (VOCs) with a photoionization detector (PID). Geologic characteristics were described on boring logs (the boring logs are presented in Appendix B). Soil was removed from the liner and placed in the appropriate sample containers. The samples were placed in a cooler

with ice until they could be analyzed by the onsite laboratory. Two samples from each point were sent to the offsite laboratory. Sample selection was based on the onsite laboratory screening results; samples with the highest concentrations of contaminants were sent to the offsite laboratory for analysis. If contaminants were not detected in any samples from a given location, the first and last sample intervals were sent for offsite laboratory analysis.

#### 4.2.4 Groundwater Screening

Groundwater samples were collected at the same locations as the soil samples at Site 12, with the hydraulic probe. Interconnected 3-foot lengths of 1.25-inch-diameter steel pipe were advanced 5 feet below the groundwater interface to ensure a sufficient supply of groundwater and allow samples to be collected. Once the sampling depth was achieved, the pipe was raised 2 feet to expose the stainless steel screen. Teflon® tubing was inserted down the inside of the pipe to the screened interval. The Teflon® tubing was equipped with a stainless steel bottom check valve. By raising and lowering the tubing at the surface, groundwater was drawn up into the tubing to the surface, approximately 8 feet, where the groundwater was collected directly into the appropriate sample containers. The samples were placed in a cooler with ice and sent to the offsite laboratory for analysis. These samples were analyzed for TPH and BTEX.

#### 4.2.5 Piezometer Installation

The three piezometers were installed using a hollow-stem auger. Continuous-flight hollow-stem augers were operated from a truck-mounted drilling rig. The augers were rotated to advance the boring and lift the formation materials (cuttings) to the surface. After drilling to the target depth of 15 feet BLS with the auger, the piezometers were installed. The piezometers were constructed of 2-inch diameter, flush threaded, schedule 40 PVC casing and screens with a 0.010-inch slot that meet ANG and State of South Dakota well construction standards. Each piezometer was completed with a 10-foot screen installed 2 feet above the water table.

The sand pack surrounding the piezometer extended from 1 foot below the bottom to 1 foot above the top of the piezometer screen. Tremie pipe conveyed properly sized, clean, bagged silica sand to the annulus. A 2-foot bentonite seal was placed above the sand pack. The

remainder of the annulus was filled with cement grout to the surface to prevent the vertical flow of water along the casing.

All piezometers were finished flush with the land surface. The PVC casing was cut 2 to 3 inches BLS and completed with a protective locking cap consisting of a cast-iron valve box assembly. The valve box was placed in the center of the hole. Each piezometer was fitted with a water-tight compression casing cap to prevent surface water infiltration. The piezometer number was clearly marked on each valve box lid and well casing. All piezometer assemblies were secured with keyed-alike brass or stainless steel locks. Construction diagrams for all piezometers are presented in Appendix C.

# 4.2.6 Monitoring Well Installation

Monitoring wells were installed using a hollow-stem auger. Monitoring wells were constructed of 4-inch inside diameter (ID), flush threaded, schedule 40 PVC casing and 0.010-inch slotted screens that meet ANG and State of South Dakota well construction standards. Monitoring wells were completed to a depth of 15 feet BLS. Each monitoring well was constructed with 2 feet of the 10-foot screen above the water table.

The sand pack surrounding the monitoring well extended from 1 foot below the bottom of the monitoring well screen to 1 foot above the top of the screen. A 2-foot bentonite seal was placed above the sand pack. The annulus above the bentonite seal was filled with cement grout to the surface to prevent the vertical flow of water along the casing.

All monitoring wells were finished flush with the land surface. The casing was cut 2 to 3 inches BLS and installed with a protective locking cap consisting of a cast-iron valve box assembly. The valve box was placed in the center of the hole with the top flush with the ground surface. Each monitoring well was fitted with a water-tight compression casing cap to prevent surface water infiltration. Each monitoring well number was clearly marked on the valve box lid and well casing. All monitoring wells were secured with keyed-alike brass locks. Construction diagrams for monitoring wells are presented in Appendix D.

### 4.2.7 Monitoring Well Development

The monitoring wells were developed within 24 to 48 hours of installation in accordance with the SI Work Plan (SAIC 1995). This interval allowed sufficient time for the grout to set. Each monitoring well was developed by surging and pumping until well water was clear and free of sand, and until specific conductivity, temperature, and pH measurements had stabilized. A calibrated meter was used to measure the temperature, pH, and specific conductivity. The development water was contained until approval for discharge to the sanitary sewer could be obtained from the city of Sioux Falls Environmental Compliance Manager. Well development forms are provided in Appendix K.

# 4.2.8 Monitoring Well Sampling

Prior to sampling, all wells were purged a minimum of five well volumes with a stainless steel submersible pump or a disposable polypropylene bailer in accordance with the SI Work Plan (SAIC 1995). Temperature, pH, and specific conductivity were measured at regular intervals as well volumes were removed. When three consecutive measurements were stable, purging was considered complete.

Groundwater samples were collected immediately after purging, using a disposable polypropylene bailer lowered into the well on a nylon rope. The groundwater was dispensed directly from the bailer into sample bottles containing a hydrochloric acid preservative. The samples were immediately placed into a cooler with ice (Appendix F provides the chain-of-custody forms that document the transfer of samples). The bailer and length of rope were disposed of after each sample was collected. The submersible pump and water level indicator were decontaminated in accordance with the SI Work Plan before each use (SAIC 1995). Appendix K provides the field sampling forms that document groundwater sampling activities.

#### 4.3 SI PROGRAM AT SITE 12 - RAMP AREA

The SI program at Site 12 - Ramp Area included an SOV survey, soil sampling using a hydraulic probe, collection of groundwater screening samples, piezometer and monitoring well

installation, and monitoring well sampling. The suspected contaminants at Site 12 included TPH and BTEX. Investigation results for Site 12 are presented in Section 5.1.

### 4.3.1 SOV Survey

Fifty SOV sampling locations were established at Site 12, as shown in Figure 4-1. Thirty-five points were placed on a grid 300 by 200 feet with a 50-foot spacing between points. This grid encompasses the previously excavated Areas 1 and 2. Some of the grid points had to be relocated in the northeast corner because a water pipe was present at shallow depth beneath Site 12. The city of Sioux Falls confirmed the location of the water line and requested that SOV sampling be conducted at least 20 feet away from the pipe's marked location.

Based on the screening results of the original 35 SOV points, 15 points were added to better define the potential contaminant source areas. Four additional points were located around point GS12-11, where total xylenes were detected (the concentration was below reporting limits). Eleven additional points were located around GS12-19, which was the only other point of the original 35 where contaminants were detected. Additional points were first located 25 feet from GS12-11 and GS12-19. If contaminants were not detected at this position, another sample was taken 12.5 feet from the original location where contaminants were detected. Contaminants were detected west of GS12-19, at grid point GS12-37. One additional sample was collected 12.5 feet to the west of GS12-19. Two samples were taken 25 feet from GS12-37, one to the north and one to the south. Three SOV sampling points were located 50 feet east of GS12-19—one point was located directly east, and the other two were located 25 feet north and south of GS12-19. A buried water line 25 feet east of GS12-19 interfered with SOV sampling at that location.

At each sampling point, three SOV samples (at 2, 4, and 6 feet BLS) were collected. The first sample was collected at a depth of 2 feet BLS due to the thickness of the concrete (8 to 16 inches) and the gravel underneath. Groundwater was encountered at approximately 7 feet BLS, which prevented SOV sampling at depths below the 6-foot interval. The SOV survey results are discussed in their entirety in Appendix A.

Figure 4-1. Field Screening Sampling Points at Site 12

24

# 4.3.2 Soil and Groundwater Screening

Based on the findings of the SOV survey and the historical groundwater flow direction, five soil sampling points were located at Site 12, as shown in Figure 4-2. Soil samples were collected as described above, at 2-foot intervals until groundwater was encountered (2 to 4, 4 to 6, and 6 to 8 feet BLS). The 0- to 2-foot interval sample was not collected because concrete (up to 16 inches thick) and the underlying gravel occupied this entire interval. One soil sample was collected at each interval for screening by the onsite laboratory. The screening data were used to select samples for analyses by the offsite laboratory. Two samples from each of the five locations were sent to the offsite laboratory (10 soil samples total at Site 12). Soil results for Site 12 are presented in Section 5.1 and Appendix A.

Groundwater screening samples were collected for offsite laboratory analysis of BTEX and TPH. Temporary well points were installed at the same five sampling locations used for soils (Figure 4-2). Samples were then collected as described in Section 4.2.4. Five groundwater samples and a duplicate were sent to the offsite laboratory. Site 12 groundwater screening results are presented in Section 5.1.

### 4.3.3 Piezometer Installation

Three piezometers were installed to provide information on groundwater flow direction. Piezometer PZ-01 is located north of Building 33, north of the ramp and the taxiway. PZ-02 is located northeast of Building 40. PZ-03 is located north of Building 36. The latter two piezometers are in the grassy area between the buildings and the ramp (see Figure 3-6). Groundwater was encountered at approximately 7 feet BLS, which is unusually high compared to groundwater elevations measured in previous months at the city of Sioux Falls production wells. The piezometer boring was drilled to 16 feet BLS. The 10-foot screen was placed between 5 and 15 feet BLS, and the sand pack was placed between 4 and 16 feet. One foot of sand was placed above the screen because of the high water level. A 2-foot bentonite seal, followed by 1 foot of grout, filled the remainder of the annulus in each piezometer. A surface pad and protective cover were installed and clearly marked, as shown in the construction diagrams presented in Appendix C.

Figure 4-2. Sampling Points at Site 12

Water levels were measured during monitoring well sampling using an electronic sounder. Water level measurements indicate that the groundwater flow direction is to the southwest. Historically, in the vicinity of Site 12, groundwater flow direction has been to the southeast or northwest, possibly induced by pumping at nearby municipal wells. The observed change in flow direction is thought to be the result of the removal of the influence of nearby production wells, since these wells are no longer in use for production.

# 4.3.4 Monitoring Well Installation and Sampling

Five wells were installed at Site 12, both downgradient and upgradient of the suspected contaminant source areas and the excavated Areas 1 and 2 (see Figure 4-2).

All monitoring wells were installed in the same manner. The boreholes for the wells were drilled to 16 feet BLS. One geotechnical soil sample was collected from each of the monitoring well borings (see Appendix J). The well screen extended from 5 to 15 feet BLS. The sand pack extended from 4 to 16 feet BLS. As with the piezometers, the bentonite seal was placed from 2 to 4 feet BLS and the grout was placed from 1 to 2 feet BLS. Well completion diagrams are presented in Appendix D.

Well development and purging was conducted as described in Section 4.2.8. Five groundwater samples were collected at Site 12 according to the procedures described in Section 4.2.

# 4.4 SI PROGRAM AT SITE 13 - MVMF

The SI program at Site 13 - MVMF included an SOV survey, soil and groundwater sampling using a hydraulic probe, monitoring well installation, and groundwater sampling. The suspected contaminants at Site 13 included TPH, BTEX, and eight common solvents, including vinyl chloride, chloroform, 1,1,1-trichloroethane, trichloroethene, 1,2-dichloroethene, tetrachloroethene, and carbon tetrachloride. The investigation results for Site 13 are presented in Section 5.2.

#### 4.4.1 SOV Survey

Six SOV survey locations were established at Site 13, as shown in Figure 4-3. Four samples were collected at each point: one each at 2, 4, 6, and 8 feet BLS. Groundwater was encountered at approximately the 8-foot interval, which prevented SOV sampling beyond this depth. Four SOV points were arranged around the pump island (one each to the north, south, east, and west). A fifth survey point was located above the underground fuel lines that supply the pumps. A sixth survey point was located between the protective posts on the south side of the island, where odors were first discovered by construction workers digging the post holes. The SOV survey results are discussed in their entirety in Appendix A.

### 4.4.2 Groundwater Screening

Twenty groundwater screening samples were collected and analyzed by the onsite laboratory for TPH, BTEX, and solvents. Groundwater sampling locations were established using a 10-foot grid system around the pump island and fuel lines, as shown in Figure 4-3. The hydraulic probe was used to insert a temporary well point whereby groundwater could be sampled. The groundwater analyses results at Site 13 are discussed in Section 5.2.3 and presented in Appendix A.

### 4.4.3 Soil Screening

Based on the results of the SOV and groundwater survey, four soil sampling locations were chosen at Site 13, as shown in Figure 4-4. At each point, samples were collected at four depths: 3 feet, 3 to 5 feet, 5 to 7 feet, and 7 to 9 feet BLS. Groundwater was encountered at approximately 9 feet BLS in this area. Samples were not collected below the water table. Two sets of samples were collected: one for the onsite laboratory and one for the offsite laboratory. After the screening sample was analyzed by the onsite laboratory, two samples per location were selected for offsite analysis. Samples with the highest concentrations of contaminants at every location were analyzed by the offsite laboratory. If the screening samples did not exhibit contamination, the first and last sample intervals were sent for offsite laboratory analyses. A minimum of two samples per location (a total of eight samples) were sent for offsite analysis from Site 13. The soil analyses results are discussed in Section 5.2.2.

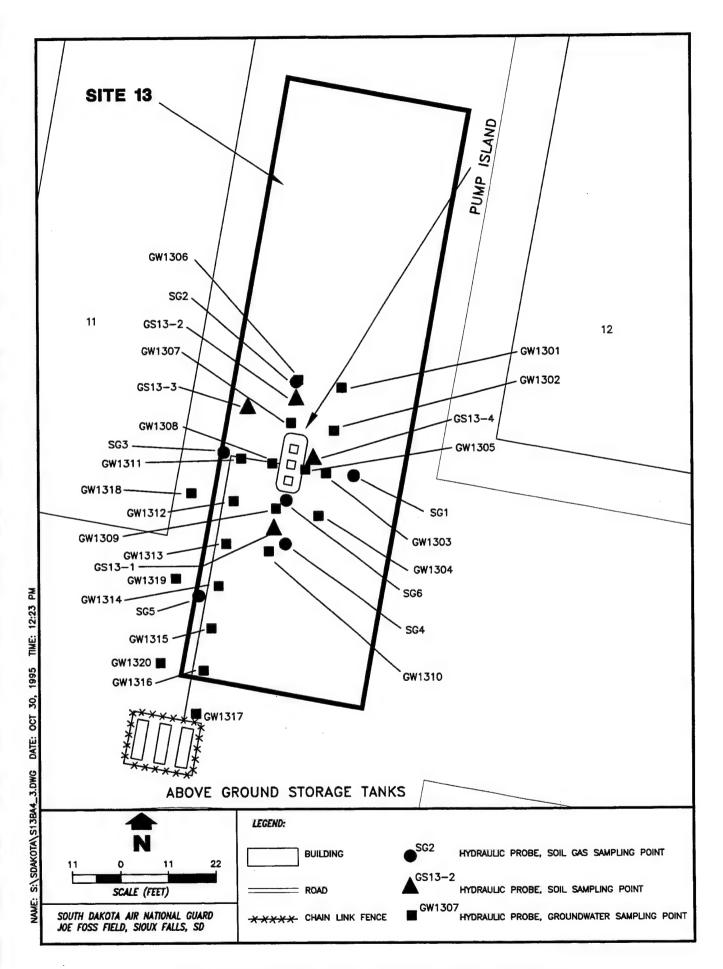

Figure 4-3. Field Screening Sampling Points at Site 13

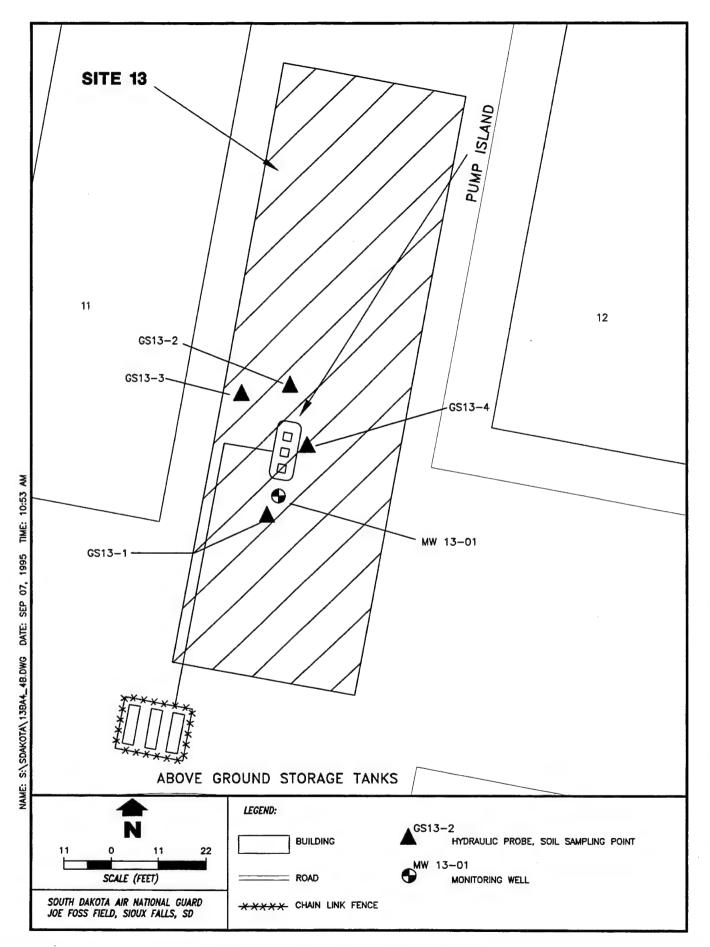

Figure 4-4. Sampling Points at Site 13

# 4.4.4 Monitoring Well Installation

One 2-inch PVC monitoring well was installed at Site 13, downgradient (southwestward) from the suspected contaminant source area. The hydraulic gradient at Site 13 is assumed to be similar to that observed at Site 12, based on the similarities in topography, geology, and the short distance between the two sites. Monitoring well MW1-13 was located at the south end of the pump island between the two protective posts, as Figure 4-4 shows. Groundwater flow is to the southwest, and MW13-1 was placed to intercept any contamination migrating from the south end of the pump island. The well boring was drilled to 20 feet BLS and completed as shown in Appendix D. A geotechnical soil sample was collected from the well boring. The geotechnical data are presented in Appendix J.

# 4.4.5 Monitoring Well Sampling

Well development and purging proceeded as described in Section 4.2. One groundwater sample and one duplicate sample were collected from well MW13-1.

# 4.5 INVESTIGATION-DERIVED WASTE HANDLING

Investigation-derived waste (IDW) for the SI at Sites 12 and 13 were handled and disposed of in accordance with state and local regulations by the SDANG Base Office of Civil Engineering.

SDANG received permission from the Utilities Department's Environmental Compliance Manager to discharge well development water into the city of Sioux Falls sanitary sewer. The conditions of the approval were as follows; 1) the volume shall not exceed 2,500 gallons, 2) the water must be placed in a container and monitored before it is discharged, 3) the wastewater must be discharged into a designated manhole, and 4) the wastes must be discharged on July 17 and 18, 1995 (see Appendix H). Approximately 1,100 gallons were discharged to the sanitary sewer. The water was pumped from the wells into a tank; no sheen was visible and the PID did not detect VOCs in the water. Well development water was discharged into the designated manhole on the dates specified.

Nineteen drums of soil cuttings were generated during piezometer and monitoring well installation. These drums were staged behind Building 47 on the blacktop parking area. The disposition of these drums was completed on August 31, 1995, following review of the soil sample analyses results. All drums were labeled to define the contents, soil borings from which the cuttings originated, and dates filled. Soil cuttings were disposed of along the airport perimeter road south of Building 10.

#### 4.6 DEVIATIONS FROM WORK PLAN

Deviations from the approved SI Work Plan (SAIC 1995) resulted in minor impacts to the scope and method of accomplishing the field program. No deviation had an impact on defining the nature and extent of contamination at Sites 12 and 13, or on data quality. All deviations were documented on field change order forms for approval by ANG (see Appendix M).

The approved SI Work Plan (SAIC 1995) specified 300 SOV samples at Site 12 and 25 SOV samples at Site 13. Because groundwater was present at depths of 7 and 9 feet BLS at Sites 12 and 13, respectively, SOV samples could not be collected at all of the proposed depth intervals. At Site 12, 152 SOV samples were collected and 24 SOV samples were collected at Site 13.

At the request of ANG, five hydraulic probe sampling points were sampled at Site 12 instead of the eight points proposed in the SI Work Plan (SAIC 1995).

At Site 12, five 4-inch monitoring wells were installed. The SI Work Plan (SAIC 1995) specified four wells in this area. This change was made at the request of ANGRC to better characterize the nature and extent of contamination at the site. Two 2-inch monitoring wells were specified in the SI Work Plan for Site 13 (SAIC 1995). Only one well was installed at the request of ANG. This decision was based on SOV and field screening results in which no major contamination was detected at the site.

Monitoring wells were completed at 15 feet BLS because of high groundwater levels instead of the proposed depth of 25 feet specified in the SI Work Plan (SAIC 1995). This change was made at the request of ANG. A related change was the completion of monitoring wells and piezometers with the sand pack extending 1 foot instead of 2 feet above the screen. This modification was made when shallower wells and piezometers were requested.

All monitoring wells were sampled using disposable polypropylene bailers rather than the reusable stainless steel bailers specified in the SI Work Plan (SAIC 1995). This change resulted in reducing the volume of decontamination fluids to be disposed of, and reduced the potential for cross-contamination of wells using incompletely decontaminated bailers.

THIS PAGE WAS INTENTIONALLY LEFT BLANK

### 5. SITE INVESTIGATION RESULTS

This section presents the results of the Site Investigation (SI) at Site 12 - Ramp Area and Site 13 - Motor Vehicle Maintenance Facility (MVMF). All data presented in this section have been validated according to U.S. Environmental Protection Agency (EPA) guidance and the Quality Assurance Project Plan (QAPP) prepared for this SI. This includes the field screening data and laboratory data for soil and groundwater samples. Soil and groundwater screening data were collected in order to identify the optimum locations for monitoring wells, and are not comparable in quality to the data from the environmental and quality control (QC) samples. Both field and laboratory analytical data have been evaluated for precision, accuracy, representativeness, comparability, and completeness (PARCC). Analytical results from the offsite laboratory (Maxim Technologies, Inc.) are provided in Appendix E. The quality of these data is considered acceptable for the purposes of this investigation. The data quality assessment is presented in Appendix J.

### 5.1 SITE 12 - RAMP AREA RESULTS

### 5.1.1 Screening Activity Results

The results of the soil organic vapor (SOV) survey and hydraulic probe activities are contained in Appendix A. The screening data indicated contamination in subsurface soils east of Area 1. Groundwater screening samples did not exhibit contamination with either benzene, toluene, ethylbenzene, and xylenes (BTEX) or total petroleum hydrocarbons (TPH).

### **5.1.1.1 SOV Survey**

TPH, ethylbenzene, and xylenes were detected in soil gas samples immediately east of Area 1. The maximum concentrations of these analytes were 391.7 micrograms per liter-volume ( $\mu$ g/L-v) TPH (4 feet BLS), and 59.2  $\mu$ g/L-v xylenes (4 feet BLS). These maximum concentrations were all located at SOV point 19, approximately 50 feet due east of the Area 1 boundary, as shown in Figure 5-1. The maximum concentration of 19.37  $\mu$ g/L-v ethylbenzene (2 feet BLS) was located at SOV point 50, approximately 12.5 feet due east of the Area 1 boundary. TPH and xylene contamination in soils, indicated by soil gas results, appears to be most widespread in the 6-foot sampling interval. No contaminants of interest were detected in

Figure 5-1. Summary of Site 12 Soil Gas Field Screening Results

the SOV samples located east of the buried water line that lies to the east of Area 1. No detectable amounts of the contaminants of interest were found during the SOV survey in the sampling locations to the north, south, or west of Area 1. Table 5-1 (page 5-4) summarizes the results of the SOV survey at Site 12.

# 5.1.1.2 Soil Screening

Five sampling locations at Site 12 were screened for TPH and BTEX. BTEX compounds were not detected in any of the samples. TPH was detected at GS05, in both the 4- and 6-foot intervals, at 5 and 10 mg/kg, respectively, as shown in Figure 5-2. TPH also was detected in the 2-foot interval at GS03, at 10 mg/kg. Table 5-2 summarizes the soil field screening results for Site 12.

Table 5-2. Site 12 Soil Field Screening\* Summary of Results

Parameter	Detection Limit	GS03-1 (2-4 ft)	GS05-2 (4-6 ft)	GS05-3 (6-8 ft)
Benzene	0.1 mg/kg	ND	ND	ND
Toluene	0.1 mg/kg	ND .	ND	ND
Ethylbenzene	0.1 mg/kg	ND	ND	ND
Total Xylenes	0.1 mg/kg	ND	ND	ND
ТРН	5 mg/kg	10	5	10

<sup>\*</sup> Analyzed by onsite laboratory.

Note: Refer to Figure 5-2 for sample locations.

#### 5.1.1.3 Groundwater Screening

Groundwater screening was conducted at Site 12 at the same locations as the soil screening sampling points. Samples were collected using the manual positive displacement method described in Section 4. The samples were sent to the offsite laboratory for BTEX and TPH analyses. TPH as gasoline was detected at 70  $\mu$ g/L in GW12-6, a duplicate of GW12-5, but not in GW12-5. No other contaminants were detected.

Table 5-1. Site 12 Soil Organic Vapor Survey Summary of Results

Domotomo	Detection Limit	SG12	SG12	SG12	SG12	SG12 43-1	SG12 46-1	SG12 46-3	SG12 47-1	SG12 47-2	SG12	SG12 49-2	SG12	SG12 50-1	SG12 50-2	SG12 50-3

Refer to Figure 5-1 for sample locations.

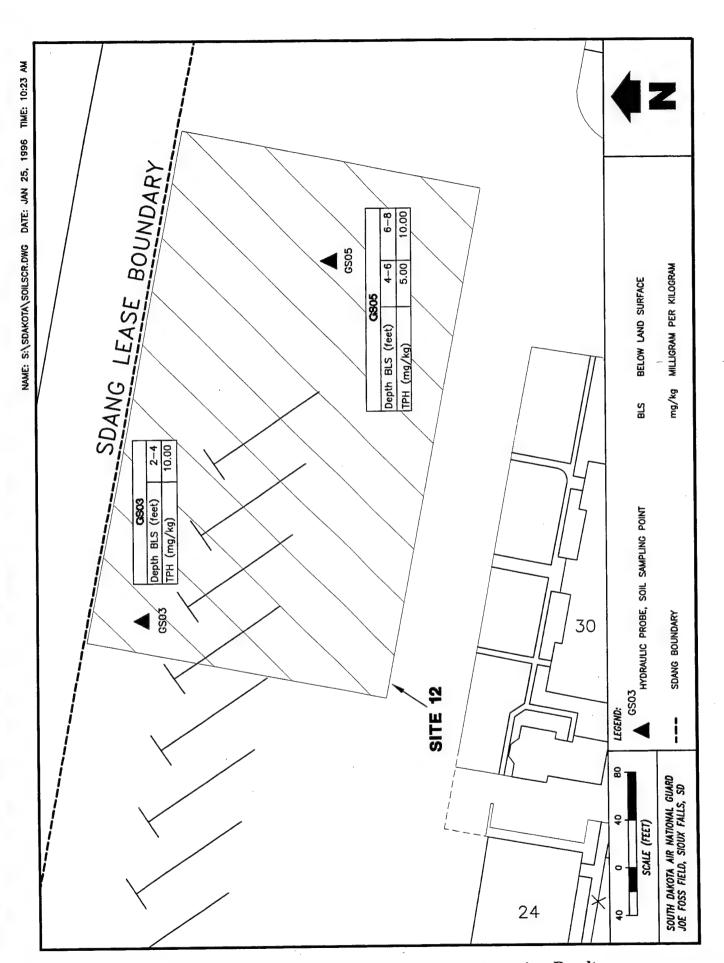

Figure 5-2. Summary of Site 12 Soil Field Screening Results

#### 5.1.2 Soils

Subsurface soil samples were collected at five locations at Site 12 for offsite laboratory analyses of BTEX and TPH. TPH as gasoline was detected in samples GS05-3 (6 to 8 feet BLS) and GS06-2 (4 to 6 feet BLS, a duplicate of GS05), at concentrations of 94 and 10  $\mu$ g/kg, respectively, as shown in Figure 5-3. Both of these measurements indicated higher boiling-point hydrocarbons that are not typical of gasoline. The sampling location is the easternmost of the five points. No other TPH or BTEX compounds were detected in soil samples at Site 12. Table 5-3 summarizes the concentrations of TPH and BTEX detected in the soil at Site 12.

Table 5-3. Site 12 Soil\* Summary of Results

Parameter	MDL	GS05-3 (6-8 ft BLS)
Benzene	1 μg/kg	ND
Toluene	1 μg/kg	ND

#### 5.1.3 Groundwater

Groundwater samples were collected from the five monitoring wells installed at Site 12 (MW12-1, MW12-2, MW12-3, MW12-4, and MW12-5). Samples were analyzed for BTEX and TPH. TPH as gasoline was detected at MW12-1 at concentrations of 81  $\mu$ g/L, and 340  $\mu$ g/L as shown in Figure 5-3. TPH or BTEX were not detected in any other groundwater sample. Table 5-4 summarizes these results.

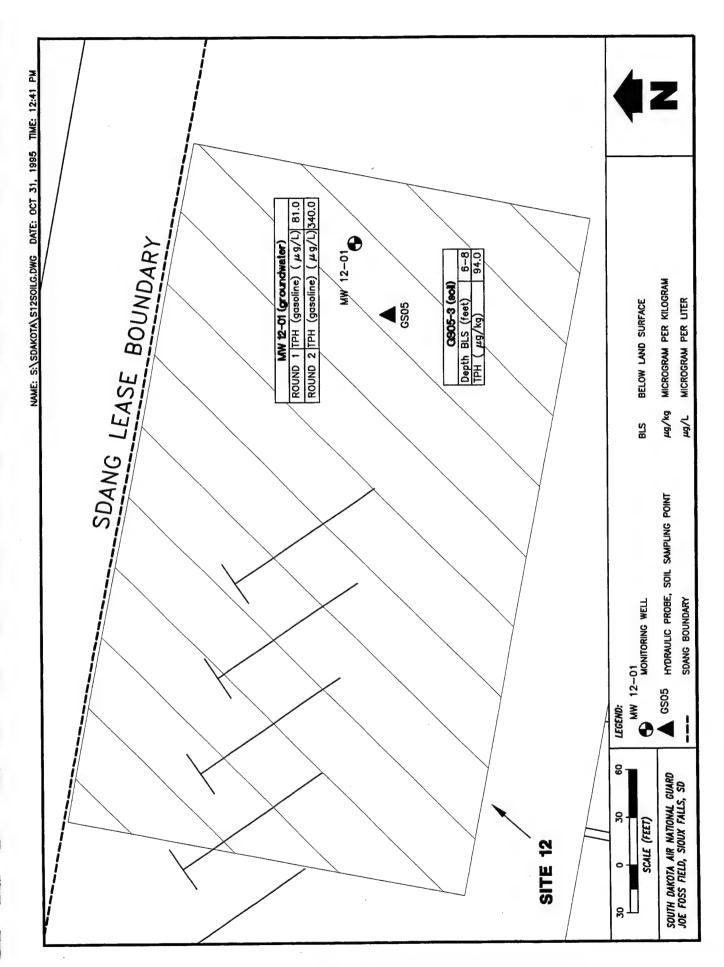

Figure 5-3. Summary of Site 12 Soil and Groundwater Results

Table 5-4. Site 12 Groundwater\* Summary of Results

Parameter	MDL	MCL	MW12-1	MW12-2

#### 5.2 SITE 13 - MVMF RESULTS

### 5.2.1 Screening Activity Results

Results of the screening activities conducted at Site 13 are reported in Appendix A.

## **5.2.1.1** SOV Survey

BTEX compounds and TPH (see Appendix A) were not detected in soil gas samples collected at Site 13.

### 5.2.1.2 Soil Screening

BTEX, TPH, and solvents were not detected in soil samples collected at Site 13.

### 5.2.1.3 Groundwater Screening

Contaminants at Site 13 were detected immediately surrounding the pump island. BTEX were detected at GW1305, approximately 9 feet due east of the pump island. The maximum concentration of any compound was 20.8  $\mu$ g/L of toluene. Toluene and xylene also were detected at GW1308, immediately west of the pump island, and GW1307, immediately north of the island, as shown in Figure 5-4 and Table 5-5. VOCs and TPH were not detected in any other groundwater sample.

Note: Refer to Figure 5-4 for sample locations.

### 5.2.2 Soils

Two soil samples were collected from each of four locations at Site 13 and analyzed for BTEX, TPH, vinyl chloride, chloroform, 1,1,1-trichloroethane, trichloroethene, 1,2-dichloroethene, tetrachloroethene, and carbon tetrachloride. These samples, designated GS13-1, GS13-2, GS13-3, and GS13-4, contained no detectable concentrations of these analytes.

#### 5.2.3 Groundwater

Monitoring well MW13-1 was sampled at Site 13 for BTEX, TPH, and eight solvents. All results for these analytes were below detection limits.

### 6. CONCLUSIONS

# 6.1 SITE 12 - RAMP AREA CONCLUSIONS

Subsurface soils immediately east of Area 1 contain detectable concentrations of benzene, toluene, ethylbenzene, and xylene (BTEX) and total petroleum hydrocarbons (TPH) in the soil vapor phase. The highest concentrations of soil vapors are located around soil organic vapor (SOV) point 19 (391.7  $\mu$ g/L-V TPH and 59.2  $\mu$ g/L-V xylenes). This point might have been the center of a spill or other release of petroleum products. The soil gas detections seem to be most areally extensive in the 6- to 8-foot sampling interval (approximately 9,000 square feet).

TPH was detected in low concentrations at two of five sampling locations (at 5 and 10 mg/kg [5 and 10 ppm] at GS03 and 5 mg/kg [5 ppm] at GS05) during field screening of soils to confirm the SOV results. No pattern of TPH distribution was apparent among the samples in which TPH was detected. Soil analysis for BTEX and TPH indicated TPH was present above detection limits only at GS05, at 94  $\mu$ g/kg (0.094 ppm). The location of GS05 coincides with SOV point 19. Petroleum odors were noticeable during sampling.

TPH was detected during groundwater screening at GW12-6 at 70  $\mu$ g/L (a duplicate sample of GW12-5). BTEX compounds were not detected during the groundwater screening. During confirmatory sampling of the five monitoring wells, TPH was detected at MW12-1, at 81  $\mu$ g/L and 340  $\mu$ g/L in two rounds of sampling. The location of GW12-5 coincides with SOV point 19.

These findings indicate that isolated areas of contamination are present in the subsurface soils. This is consistent with the Geotek investigation conducted in 1993. TPH contamination in soils may be impacting groundwater quality at Site 12, especially in the area immediately east of Area 1. However, contaminant levels in soils are below the South Dakota Department of Environment and Natural Resources (DENR) cleanup levels. Maximum contaminant levels (MCLs) for BTEX compounds were not exceeded in groundwater. However, one occurrence of TPH (340  $\mu$ g/L at MW12-1) exceeds the South Dakota standard of 100  $\mu$ g/L for wellhead protection areas.

## 6.2 SITE 13 - MOTOR VEHICLE MAINTENANCE FACILITY CONCLUSIONS

BTEX compounds, TPH, and organic solvents were not detected during the SOV survey and soil screening at Site 13. These analytes were not detected during offsite laboratory analysis of soils at four locations at Site 13.

BTEX compounds were detected at low concentrations in groundwater screening samples obtained from the immediate area of the pump island, at Geoprobe locations GW1305, GW1307, and GW1308. TPH and solvents were not present above detection limits. No analytes above detection limits were detected during offsite laboratory analysis of the groundwater sample from monitoring well GW1-13-01, located downgradient from the Geoprobe points.

### 7. RECOMMENDATIONS

# 7.1 SITE 12 - RAMP AREA RECOMMENDATIONS

Isolated areas of low-level contamination have been identified in subsurface soils and groundwater at Site 12. This contamination is present in the area immediately east of Area 1, and at one point in the northwestern corner of the site. Soil organic vapor (SOV) data indicate that a potential source is or was located in soils at or near SOV point 19, immediately east of Area 1. Noticeable odors of petroleum were present during soil and water sampling at Site 12. Soil samples collected at Site 12 contained total petroleum hydrocarbons (TPH) at concentrations below the South Dakota Department of Environment and Natural Resources (DENR) cleanup level of 100 mg/kg.

TPH were detected in one of the five monitoring wells sampled. Concentrations of TPH were below maximum contaminant levels (MCLs) or the South Dakota requirements for wellhead protection areas with one exception (340  $\mu$ g/L at MW12-1). The groundwater analytical results do not indicate that the TPH is migrating.

The results indicate that contamination is present in the soils and that groundwater quality is locally affected. Therefore, it is recommended that the Air National Guard (ANG) continue groundwater monitoring on a quarterly basis. Groundwater samples were collected from Site 12 in June and July 1995. Three additional rounds of groundwater samples will be collected in February, May, and August 1996. The samples will be analyzed for TPH and benzene, toluene, ethylbenzene, and xylene (BTEX). Continued monitoring will expand the data set for groundwater at Site 12, allowing ANG to determine temporal and spatial variations in TPH concentrations. The data should allow ANG to evaluate whether soil contamination east of Area 1 impacts the groundwater sufficiently to warrant further study.

# 7.2 SITE 13 - MOTOR VEHICLE MAINTENANCE FACILITY RECOMMENDATIONS

TPH, solvents, and BTEX compounds were not detected during soil gas, soil, and groundwater analyses at Site 13. Although BTEX compounds were present at low concentrations in three groundwater screening locations, none was detected in the sample from the monitoring

well installed at Site 13. BTEX concentrations in groundwater did not exceed MCLs. Because of these findings, Site 13 is recommended for no further action. A decision document recommending no further action should be prepared for Site 13. This recommendation is consistent with the observed low levels of contamination.

## Introduction

SAIC contracted TARGET Environmental Services, Inc. (TARGET) to perform a site screening survey at Joe Foss Field, an active municipal airfield shared by the National Guard and civilian aviators in Sioux Falls, South Dakota. The study area actually includes two sites: the Area 12 Site - Ramp Area and the Area 13 Site - Motor Vehicle Maintenance Facility. Under the direction of SAIC personnel a total of 176 soil gas, 32 soil and 26 groundwater samples were collected at the site. All of the samples except for 5 groundwater samples were analyzed for benzene, toluene, ethylbenzene, xylenes (BTEX) and total petroleum hydrocarbons (TPH). Area 13 Site samples were also analyzed for solvent. The field phase of the survey was performed on June 8-15, 1995.

# Sample Collection and Analysis

Soil gas, soil and groundwater samples were collected at multiple depths at the locations shown in Figures 1 through 3. Soil gas samples were collected at 2-foot intervals as deep as 8 feet, soil samples were collected over 2-foot intervals as deep as 9 feet, and groundwater samples were generally collected from 10 to 12 feet.

Prior to the collection of each soil gas sample, the entire sampling system (including downhole probe, tubing, syringe, and all associated plumbing) was purged with ambient air drawn through an organic vapor filter cartridge. An electric hammer drill was used to penetrate pavement where necessary. To collect the samples, a truck-mounted hydraulic probe was used to advance connected 3-foot sections of 1" to 1.5" OD threaded steel casing down to the sampling depth. Once at depth, the casing was hydraulically raised a fraction of an inch to release a disposable drive point and open the bottom of the casing. A teflon line with a hollow stainless

steel probe end was inserted into the casing to the bottom of the hole, and threaded through a plug which isolates the bottom-hole sampling chamber from the up-hole annulus. A sample of in-situ soil gas was then withdrawn through the probe and used to purge atmospheric air from the sampling system. A second sample of soil gas was withdrawn through the probe and encapsulated in a pre-evacuated glass vial at two atmospheres of pressure (15 psig). The self-sealing vial was detached from the sampling system, packaged, labeled, and stored for laboratory analysis. Deeper samples within the same boring were collected by readvancing the casing with the disposable drive point leading. All sampling holes were backfilled with bentonite and the surface repaired with like material upon completion of the sampling.

Prior to the day's field activities all sampling equipment and probes were decontaminated by washing with a Liquinox/distilled water solution and rinsing thoroughly with distilled water. Internal surfaces were air-dried, and external surfaces were wiped clean using clean paper towels.

To collect the soil samples, a the hydraulic probe was used to advance a 24" long, 1.25" to 1.75" OD steel sampling tube (equipped with an acetate liner and a piston stop tip) attached to connected sections of casing down to the sampling depth. An electric hammer drill was used to penetrate pavement where necessary. The piston stop was then released and the pipe driven an additional 2 feet, allowing soil to enter the sampling tube. The sampling tube was retrieved, and the liner containing the soil core was removed from the casing. The soil was then extruded into glass jars, which were sealed with teflon-lined caps, labeled and relinquished to TEG's on-site mobile laboratory for analysis. The sampling tube was decontaminated by scrubbing with a solution of Liquinox/distilled water, rinsing with distilled water and drying with clean paper towels prior to reuse. A new liner was used for each sample.

To collect the groundwater samples, the hydraulic probe was used to advance steel casing to the sampling depth. An electric hammer drill was used to penetrate pavement where necessary. The steel casing was removed and connected 5-foot sections of 1/2" PVC slotted screen and riser were inserted to the full depth of the hole. A water level sensor was used to detect the surface of the groundwater table and to ensure that a sufficient amount of water had entered the pipe to complete a sample. The water level sensor was removed and the sample was collected using one of two methods. At locations in Area 12, an up-and-down motion was manually applied to a length of teflon tubing fitted at its lower end with a stainless steel ball check valve and inserted down into the casing to the groundwater table, in essence pumping the water using positive displacement. At Area 13 Site, a 21" long by 7/16" O.D. stainless steel bailer was used to collect the sample. Samples were placed in 40 ml glass vials, which were sealed, labeled and relinquished to TEG's on-site mobile laboratory for analysis.

Prior to the day's field activities and after collection of each sample, the steel casing and the bailer or teflon sampling tube were decontaminated by washing with a solution of Liquinox/distilled water, rinsing with distilled water and drying with filtered ambient air to ensure discrete sampling. New sections of PVC slotted screen and riser were used for each groundwater sampling location.

The samples selected for analysis by TEG were analyzed according to the following EPA Methods:

TPH:

8015 modified

BTEX:

8020

Solvent:

3810/8010

# Quality Assurance/Quality Control (QA/QC) Evaluation

# Field QA/QC Samples

Soil gas field control samples (blanks) were collected at the beginning and end of each day's field activities, between sites and after every twentieth sample. These QA/QC blanks were obtained by filtering ambient air through a dust and organic vapor filter cartridge and encapsulating as described in the "Field Procedures" in Appendix A. An equipment rinseate blank was collected after groundwater sampling at the Area 13 Site by rinsing distilled water through the decontaminated bailer into sample vials as previously described. The laboratory results for these samples are reported in the attached data tables in their order of collection with the field samples. Concentrations of all analytes were below the detection limit in all field control blanks, indicating that the QA/QC measures employed were sufficient to prevent crosscontamination of the samples during collection. Laboratory QA/QC is presented as received in the attached data tables.

### Results

In order to provide graphic presentation of the results, individual data sets from the attached data tables with data above detection limits have been mapped and contoured to produce Figures 4 through 19. Map sample points with no data shown indicate that the analyte concentrations in the sample were below the detection limit. Area 12 soil samples were too far apart and too irregularly spaced to facilitate contouring, although the data was mapped. Area 13 soil samples yielded no detectable concentrations of BTEX or TPH and were therefore not mapped.

Ms. Virginia VerMulm
Maxim/Huntingdon Sioux Falls
601 E. 48th Street N.
Sioux Falls, South Dakota 57104-0698

Dear Ms. VerMulm:

On June 20, 1995, Huntingdon/St.Louis received two water samples and nine soil samples for Volatile Organic analysis. The samples received are:

St.Louis No.	Sioux Falls No.
95003032	95-5396;EB04
95003033	95-5399;TB03
95003034	95-5480;GS13-1-1
95003035	95-5481;GS13-1-4
95003036	95-5482;GS13-2-1
95003037	95-5483;GS13-2-4
95003038	95-5484;GS13-3-1
95003039	95-5485;GS13-3-4
95003040	95-5486;GS13-4-2
95003041	95-5487;GS13-4-4
95003042	95-5488;GS13-4-5

The samples were analyzed using the EPA OLMO1 statement of work. A CLP deliverable is provided. All calibrations, surrogates, internal standards, matrix spike/duplicates, method blanks and lab control samples met the required QC controls.

If you have any questions about this data package, please call me at (314) 426-0880.

Sincerely,

Marti Ward

APPENDIX G. SI DATA REQUIREMENTS FOR FEDERAL FACILITY DOCKET SITES

THIS PAGE WAS INTENTIONALLY LEFT BLANK

### SI DATA REQUIREMENTS FOR FEDERAL FACILITY DOCKET SITES

- Supply copies of all sampling data, onsite and offsite, including location map, detection limits, raw data sheets, quality assurance/quality control (QA/QC) documents, date(s) sampled, analytical method(s) used, well or boring logs, and sampling technique(s).
- 2. Locate and identify on a map all known or suspected sources. Supply all information about source(s), such as: dates of operations, use, or spillage; amounts of material deposited, stores, or spilled; dimensions of source(s); known or suspected hazardous substances.
- 3. Provide a description of all aquifers beneath the site, including description of overlying materials, depth first encountered, thickness, and composition.
- 4. Provide the location of all drinking water wells within a 4-mile radius from the site (property boundary) and locate the wells within a 1-mile radius on a 7.5-minute topographic map. Provide information on depth of well(s), screening interval(s), depth of aquifer(s) encountered, population served for multiple wells (i.e., municipal system), provide the number of wells, average annual pumpage of each well, and total population served by system. Include information on all standby wells.
- 5. Provide information and location (on a 7.5-minute topographic map) of wells within 4 miles that are used to irrigate five or more acres of commercial food or forage crops, or watering of commercial livestock, or ingredient in commercial food preparation, or supply for aquaculture, or supply for a major or designated water recreation area, excluding drinking water use.
- 6. Provide average number of persons per residence for county (or counties) that the site is located in per the U.S. Census Bureau.
- 7. Identify and locate all surface water bodies within 2 miles of the site marking off the drainage routed (shown on a 7.5-minute topographic map) from each source to applicable surface water bodies. Provide the average annual cubic feet per second flow for each surface water body within 15 miles downriver or radius from the point of probable entry into surface water. For lakes, provide information on inflow and outflow.
- 8. Provide the number of acres in each drainage basin.
- 9. Provide the 2-year, 24-hour rainfall.
- 10. Provide the location of all drinking water intakes within 15 downstream miles (rivers) or 15-mile radius (lakes, bays, etc.). Provide information on population served. For multiple intakes (i.e., municipal system), provide information on the number of intakes, location of all intakes (regardless of 15-mile limit), and total population served by system. Include information on all standby intakes.

- Provide information and location of intakes within 15 miles downriver (radius in lake or bay) that are used to irrigate five or more acres of commercial food or forage crops, or watering of commercial livestock, or ingredient in commercial food preparation, or supply for aquaculture, or supply for a major or designated water recreation area, excluding drinking water use.
- 12. Provide any surface water body 15 miles downriver (radius in lakes or bay) used for drinking water.
- 13. Provide the average human food chain production (pounds per year) for each surface water body 15 miles downriver of 15-mile radius in lake.
- Within a 4-mile radius from the site and 15 miles downriver, or radius in lake, identify all sensitive environments that exist. Provide original documentation (U.S. Fish and Wildlife Service [USFWS], Natural Heritage Database, state agencies, National Oceanographic and Atmospheric Administration [NOAA], etc.), multiple sensitive environments within a sensitive environment.
- 15. What is the linear frontage of all wetlands 15 miles downriver or 15-mile radius in lake?
- 16. Provide the location and number of persons residing, working, attending school, or day care within 200 feet.
- 17. Identify all terrestrial sensitive environments that exist onsite. Provide original documentation (USFWS) Natural Heritage Database, state agencies, NOAA, etc.) and locate each on a 7.5-minute topographic map. Note that there could be multiple sensitive environments within a sensitive environment.
- 18. Provide the total number of people in the following distance rings from source(s)?
  - 0 1/4 mile
  - 1/4 1/2 mile
  - 1/2 1 mile
  - 1 2 miles
  - 2 3 miles
  - 3 4 miles.

Use 1990 Census data and/or actual house counts. Document how calculated.

- 19. Provide the location and area (in acres) of all wetlands within 4 miles of the site.
- 20. Contact U.S. Environmental Protection Agency (EPA) Regional Office immediately if any radionuclides are present or suspected at the site and supply all radiological information known to date.
- 21. For all of the above information, use primary data source and supply two copies or specify where copies may be obtained.

- 22. Provide any removais or remedial actions taken place at the site.
- 23. If information relevant to a question already has been provided to EPA, your answer may precisely cite the previous submittal by title, date, page, and paragraph number rather than resubmitting the information.

Hearing Impaired (605) 339-7039

July 11, 1995

Captain Alvin Punt, SDANG 114 FG/EM 1201 W Algonquin St. PO Box 5044 Sioux Falls, SD 57117-5044

FACSIMILE

Dear Capt. Punt:

On July 10, 1995, I received a letter from you requesting an approval for a special discharge. You requested permission to discharge approximately 2000 gallons of water produced in the development of four new monitoring wells at your site. In a phone conversation you stated that you did not expect water to be contaminated except possibly very low levels of hydrocarbons.

I have reviewed your request along with the localized groundwater monitoring results that you submitted. I hereby give a temporary conditional approval to discharge the well development water into the City's sanitary sewer. Discharge is approved upon meeting the following conditions:

- 1. Wastewater volume shall not exceed 2,500 gallons;
- 2. Wastewater must be placed in a receptacle for monitoring before discharge;
- 3. Required Monitoring:

Visual Inspection - must not have a visual sheen

Monitor headspace above water in receptacle - < 5 % LEL

- Wastewater must be discharged at manhole designated in your request;
- 5. Discharge is approved between July 12 and July 19, 1995;
- 6. This is a one time conditional approval specific to your request.

If you have any questions or comments on this matter, please contact my office 339-7088.

Sincerely,

Robert J. Kappel

Environmental Compliance Manager

Lappel

DATA QUALITY ASSESSMENT

THIS PAGE WAS INTENTIONALLY LEFT BLANK

### APPENDIX I. DATA QUALITY ASSESSMENT

### I.1 INTRODUCTION

A comprehensive quality assurance/quality control (QA/QC) program was followed during the Site Inspection (SI) conducted for Site 12 - Ramp Area and Site 13 - Motor Vehicle Maintenance Facility (MVMF) at the South Dakota Air National Guard (SDANG), Joe Foss Field located in Sioux Falls, South Dakota, to ensure that analytical results and the decisions based on these results are representative of the environmental condition at the sites. objectives of the SI were to investigate the presence or absence of environmental contamination, and collect and analyze sufficient numbers of samples to support recommendations for further investigation or corrective actions. The following documents were utilized during the evaluation of the QC data: the U.S. Environmental Protection Agency (EPA) Level III; QC requirements contained within the guidelines and specifications presented in the Quality Assurance Project Plan (QAPP) (May 1995) submitted as part of the project plans prepared by Science Applications International Corporation (SAIC); the EPA Contract Laboratory Program (CLP) Statement of Work for Organics Analysis; and the EPA Laboratory Data Validation Functional Guidelines for Evaluating Organics (1988). The number of soil and groundwater samples collected during the SI, in addition to the numbers of field QC samples collected and selected laboratory QC samples (i.e., matrix spikes/matrix spike duplicates [MS/MSDs]) analyzed, are presented in Tables I-1a and I-1b. The data validation worksheets are referenced within the subsection describing the applicable analysis. The QC checks and results are summarized below.

### I.1.1 Data Quality Objectives

A comparison of the SI analytical results to project data quality objectives (DQOs) as defined in the QAPP formed the basis for evaluating the quality of the analytical data. As described in the QAPP, analytical data must be of a known and acceptable quality in order to be used to evaluate contamination at MVMF. DQOs are qualitative and quantitative indicators of data quality. DQOs were established during the initial scoping process to guide the implementation of the field sampling and laboratory analyses for the SI. A QA program was established to standardize procedures and document activities. The program provided a means to detect and correct any deficiencies in the process. DQOs are set to define and establish the

criteria against the fitness of the data. Both quantitative and qualitative DQOs were established for the SI. Data verification and validation of 100 percent of the resulting analytical data packages ensured that Maxim Technologies, Inc. (MT) produced an acceptable quality level for results. Field activities affecting precision and accuracy were controlled by strict adherence to approved standard operating procedures (SOPs) and documentation of the field tasks. Field logbooks noted exceptions to the procedures and chain-of-custody records tracked sample shipments and receipt of these shipments by MT. These results confirmed that no cross-contamination due to sample handling practices or inadequate equipment decontamination occurred. Sampling precision was estimated by the analysis of field duplicate samples. Indicators used to assess both field and laboratory data quality include precision, accuracy, representativeness, comparability, and completeness (PARCC). The following sections summarize the DQOs for the PARCC parameters obtained during the SI.

### I.1.1.1 Precision

Precision is a measure of the closeness with which multiple analyses of a given sample agree with each other. It can be defined as the agreement between the numerical values of two or more measurements that have been under identical conditions. Precision can thus be seen as a measure of the magnitude of errors. The overall precision of the measurement data is a mixture of sampling and analytical factors. Analytical precision can be measured through the analysis of MS/MSDs, and sampling precision and spatial variability of contamination can be assessed through the analysis of the field duplicates. Precision is stated in terms of standard deviation, coefficient of variation, range, and relative percent difference (RPD). The RPD between results of duplicate samples for a given compound or element traditionally has been used to assess precision between two samples. The RPD is defined as the ratio of the absolute value of the difference between two results and the mean of the results. RPD was calculated using the following equation:

$$\frac{/C_1 - C_2/}{\left(\frac{C_1 + C_2}{2}\right)} \times 100$$

where:

 $C_1$  = Concentration of the compound or element in the sample

 $C_2$  = Concentration of the compound or element in the duplicate/replicate.

When the RPD approaches zero, complete agreement is achieved between duplicate sample pairs, indicating a high degree of precision.

The RPDs of the MS/MSD samples is the first type of QC sample used to assess the precision of the data quality. The laboratory selected 1 sample in 20 and split the sample into 3 sample portions. MS/MSD samples were prepared by routinely analyzing the first portion for the parameters of interest, while the remaining two portions were spiked with known quantities of the parameters of interest before analysis. The RPD between the spike results was calculated and used as an indication of the analytical precision for the solvents; benzene, toluene, ethylbenzene, and xylenes (BTEX), total petroleum hydrocarbons (TPH) as gasoline; and TPH as extractables.

All RPD values calculated from the solvents (7 values reviewed), BTEX and TPH as gasoline (12 reviewed values), and TPH as extractables (2 reviewed values) soil MS/MSD analyses were within the methods control limits. Since each analysis was evaluated according to the required QC criteria described in Section I.3 and all of these criteria were met for the environmental samples analyzed, these RPD values are considered to be a more representative reflection of the variability characteristic of the environmental condition at MVMF, and as a result, the analytical DQO for solvents, BTEX, and TPH precision is considered to have been met. Overall, the analytical precision DQO for those analyses is considered to have been met. The analytical QC criteria used to evaluate analytical precision and all MS/MSD results are discussed in Section I.3.

The second type of QC sample, field duplicate samples, was included as part of the SI. Field duplicate samples assess the precision of the sampling techniques and spatial variability of the contamination. Field duplicates were collected using the same techniques as those used to collect the environmental samples. Field duplicates were collected at a rate of 1 duplicate per

10 field samples per matrix for each parameter. No corrective action was taken based on RPD results. Field RPD values were calculated only for compounds detected in concentrations greater than the contract required quantitation limits (CRQLs) and method detection limits (MDLs) in both replicate pair samples or in one sample. No specific control limits for field precision were established in part because the natural heterogeneity of the environmental media was much greater than the variability imparted by field activities.

No solvents, BTEX, and TPH as extractables were detected in soil and groundwater field duplicates. TPH as gasoline was detected in one soil field duplicate (i.e., GS6-2) and one groundwater field duplicate (i.e., GW12-6) collected from Site 12. RPD values were 200 percent for TPH as gasoline. These are attributable to TPH as gasoline concentrations being near the MDL in the field samples.

Overall, project precision for environmental analyses has been determined to be adequate for the uses of the analytical data, which were to identify the contaminants and provide an assessment of the distribution of each compound in both soil and water matrices. Section I.2 presents a comprehensive discussion of all field duplicate sample results.

### I.1.1.2 Accuracy

Accuracy is the closeness of agreement between an observed result and the true value for a sample analysis. Accuracy can be evaluated for a particular method by measuring the agreement between an observed result from analysis of a reference standard with an analytical lot and its certified value. Accuracy is usually expressed in terms of bias (high or low). Bias is assessed by the percent recovery of a compound or element that has been added to the QC sample or environmental sample prior to analysis. Sampling accuracy is assessed by evaluating the results of the trip blanks, field blanks, and equipment blanks; analytical accuracy is assessed through the use of MS/MSDs. Analytical accuracy is expressed as the percent recovery of a

compound or element that has been added to the environmental sample at a known concentration before analysis. The percent recovery values were calculated using the following equation:

$$\frac{S_s - S_o}{S_a} \times 100$$

where:

S<sub>s</sub> = Total compound or element concentration detected in the spiked sample

 $S_{o}$  = Concentration of the compound or element detected in the unspiked sample

S<sub>a</sub> = Concentration of the compound or element added to the sample.

Analytical accuracy for this project was measured through the use of surrogate field samples and MS/MSD samples. Each type of spike provided different information on the accuracy of the measurement system.

The percent recoveries of the surrogates for solvents, BTEX, TPH as gasoline, and TPH as extractables analyses were the first type of QC used to assess the accuracy of the data quality. Surrogate compounds spiked into field samples provide information on the efficiency of all steps of the gas chromatography/mass spectrometry (GC/MS) and GC methods in recovering these compounds from the individual sample matrices. In the EPA analytical program, surrogate recoveries are used to determine if an analytical method is in control and to obtain information on recovery effects in the environmental matrix. The QC limits for recovery of all surrogates for soil and water environmental samples for solvents were those established for the EPA CLP. The QC limits for recovery of all surrogates for soil and water environmental samples for BTEX and TPH extractables were those established by the laboratory for SW Method 8020 and Hazardous Materials Laboratory, California Department of Health Services (CAL DHS) method. All surrogate percent recoveries were within the applicable control limits. All supporting volatile organic compound (VOC) and TPH information cited above also was qualitatively evaluated with respect to the analytical accuracy DQO.

The percent recoveries of the MS/MSD for solvents, BTEX, TPH as gasoline, and TPH as extractables analyses was the second type of QC used to assess the accuracy of the data quality. Accuracy determined by MS/MSD samples is a function of both matrix and method. All VOC MS/MSD percent recoveries were within the control limits. Recovery values of two out of four reviewed TPH as extractables MS/MSD results were above the 125 percent limit. Above upper limit recoveries in the natural matrix spikes indicate possible interferences and possible high bias data. Despite these values, no systematic laboratory error was detected; however, the results are considered to have little impact on the overall environmental data quality. All supporting metals QC information cited above also was qualitatively evaluated with respect to the analytical accuracy DQO. Based on the evaluation of the MS/MSD results and the associated laboratory QC results summarized in Section I.3 on a project-wide basis, the laboratory accuracy has been determined to be acceptable for all analyses, and as such, the analytical DOO for accuracy was met, except where noted.

Sampling accuracy was maximized by the adherence to the strict QA program presented in the SI QAPP. All procedures (i.e., soil boring and groundwater sample collection); equipment decontamination; and health monitoring equipment calibration and operation) used during the SI were documented in the QAPP. Field QC blanks (i.e., trip blanks, field blanks, and equipment blanks) were prepared to ensure that all samples represent the particular site from which they were collected, assess any cross-contamination that may have occurred, and qualify the associated analytical data accordingly.

During the sampling program, approximately 14 percent of the samples collected during the program were field QC blanks (i.e., trip blanks, field blanks, and equipment blanks) obtained to determine the degree of cross-contamination or ensure successful decontamination procedures. Based on an evaluation of the compounds detected in the field QC blanks, the overall field accuracy is acceptable. As a result, the field DQO for accuracy is considered to have been met. A comprehensive discussion of the field QC results is presented in Section I.2.

### I.1.1.3 Representativeness

Representativeness is defined as the degree to which the data accurately and precisely represent a characteristic of a population, parameter variations at a sampling location, a process condition, or an environmental condition. Representativeness is the qualitative parameter concerned most with the proper design of the sampling program. The selected sampling methods ensure that an environmental sample accurately represents the characteristic population from which it was obtained. Although considerable information was available regarding the historical activities conducted at the SI sites, potential contaminant source areas within the sites were not well-defined at all of the sites. Soil samples were collected from areas suspected of having the highest potential for contamination and to obtain areal coverage of the sites. Factors that affect the representativeness of the analytical data include improper preservation, holding times, use of standard analytical methods, and matrix or analyte interferences. Holding times and preservation criteria are based on the most restrictive holding times recommended by EPA for water and soil matrices. Sample representativeness was ensured during the SI by collecting sufficient samples of a population medium, properly distributed with respect to location and time. Representativeness was assessed by reviewing the drilling techniques and equipment, sample collection methods, equipment, and sample containers used during the SI, in addition to evaluating the RPD values calculated from the duplicate samples. The reproducibility of a representative set of samples reflects the degree of heterogeneity of the sampled medium, as well as the effectiveness of the sample collection techniques. Intervals for soil sampling were chosen to obtain the strata with the highest concentrations of contaminants in order to achieve the most conservative representation and to optimize the number of samples required.

Based on the evaluation of the factors described above and summarized in Section I.3, the samples collected during the SI are considered to be representative of the environmental condition at SDANG.

### I.1.1.4 Comparability

Comparability is a qualitative parameter expressing the confidence with which one data set can be compared to another and is limited to the other PARCC parameters, because only when precision and accuracy are known can one data set be compared to another. Quantitative

criteria for determining if representativeness has been achieved are not specifically stated. To optimize comparability, only the specific methods and protocols that were specified in the QAPP were used to collect and analyze samples during the SI at MVMF. By using consistent sampling and analysis procedures, all data sets were comparable within the sites at SDANG, between sites at the installation, or among U.S. Army facilities nationwide, to ensure that remedial action decisions and priorities were based on a consistent data base. Comparability also was ensured by the analysis of EPA reference materials, establishing that the analytical procedures used were generating valid data. The SI utilized one laboratory to perform the analyses and the same sampling method for each medium. All samples collected for VOCs (i.e., solvents) were analyzed using the EPA CLP statement of work (SOW), BTEX and TPH as gasoline were analyzed using EPA solid waste methods. TPH as extractables was analyzed using CAL DHS method. Based on the precision and accuracy assessment presented above, the data collected during the SI are considered to be comparable with the data collected during previous investigations.

### I.1.1.5 Completeness

Completeness is defined as the percentage of valid data obtained from the sampling and analysis process. For data to be considered valid, they must have met all acceptance criteria, including accuracy and precision, as well as any other criteria specified by the analytical methods used.

Furthermore, project completeness is defined as the percentage of data used to prepare a preliminary human health-based risk evaluation and upon which recommendations for site remediation are based. For analytical data to be considered usable for the preliminary risk evaluation and remediation recommendations, each data point must be satisfactorily validated. Results that have been flagged for various reasons may be considered to have encountered minor problems with limited impact on the data quality. The completeness of both laboratory analyses and sampling will be evaluated for each site. DQOs for the SI at MVMF were set at 95 percent for both the field sampling and laboratory completeness.

Site 12—Based on an evaluation of the laboratory QC, 100 percent of the BTEX and TPH data points were used as a basis for evaluating the magnitude and extent of contamination. Field completeness for soil and groundwater samples was 100 percent. Eleven soil boring samples and 14 groundwater samples were planned and actually collected from Site 12.

Site 13—The laboratory completeness for BTEX, solvents, and TPH analyses was 100 percent. Based on the evaluation of the field sampling, field completeness was 100 percent for Site 13. Nine soil borings samples and eight groundwater samples were scheduled and actually collected at Site 13.

### I.2 FIELD QUALITY CONTROL ASSESSMENT

During all phases of the SI sampling program, QC samples were collected to gauge the impacts from various components of field activities. Approximately 18 percent of the samples collected during the program were QC samples obtained to determine the degree of cross-contamination, ensure successful decontamination procedures, or determine the effects of media heterogeneity on results. Six trip blanks, six field blanks, five equipment blanks, and five field duplicates (i.e., two soil and three groundwater) were collected and analyzed for the same compounds and using the same laboratory techniques as those used to analyze the environmental samples. Trip blanks, field blanks, and equipment blanks provide a measure of various sources of cross-contamination, decontamination efficiency, and any other potential error that can be introduced from sources other than the sample. Table I-2 contains a cross-reference of environmental samples to the associated field QC blank sample.

### I.2.1 Trip Blanks

Trip blanks were collected to determine if cross-contamination of VOCs occurred during sample handling or shipment of environmental samples to the laboratory. Trip blanks were prepared by MT, located in Sioux Falls, South Dakota. Each trip blank consisted of two volatile organic analysis (VOA) vials per shipping cooler. These blanks were prepared with organic-free reagent water, sent to SDANG, stored with the unused sample bottles, and returned to the laboratory with each cooler containing environmental samples to be analyzed for VOCs (i.e., solvents and BTEX). Trip blanks were analyzed by EPA CLP OLMO1 SOW (solvents)

and SW8020 (BTEX). Table I-3 summarizes the concentrations of the detected solvents and VOCs in the trip blanks collected during the SI.

Solvents Analyses—Four trip blanks were collected and analyzed for solvents using EPA CLP OLMO1 SOW. Analytical results show that 1,1,1-trichloroethane was detected in one trip blank (i.e., TB02) at a concentration below the CRQL. The presence of 1,1,1-trichloroethane is not considered to be representative of environmental conditions at SDANG, since this solvent was not detected in the associated environmental samples.

BTEX Analyses—Six trip blanks were collected and analyzed for BTEX using EPA SW Method 8020. Analytical results show that BTEX were not detected in any trip blank.

### I.2.2 Field Blanks

Field blanks were collected to provide baseline analytical data for the water used for equipment decontamination (i.e., American Society for Testing and Materials [ASTM] Type II reagent water) and in the steamcleaner equipment (i.e., potable water). Field blanks were collected by randomly selecting sample containers from the supply, filling them with the appropriate water source, and than preserving and analyzed these blanks for the same compounds and using the same laboratory methods as those used for the associated environmental samples. Table I-4 summarizes the concentrations of the detected compounds in the field blanks collected during the SI.

Solvents Analyses—Six field blanks were collected and analyzed for solvents using EPA CLP OLMO1 SOW. No unacceptable level of contamination was detected in the field blanks. Contamination was limited to two compounds: 1,1,1-trichloroethane and chloroform. 1,1,1-Trichloroethane (i.e., 2  $\mu$ g/L) was detected in one field blank. Chloroform was detected in four field blanks, with a minimum concentration of 2  $\mu$ g/L and a maximum of 34  $\mu$ g/L. Since these solvents have not been detected in the associated environmental samples, no data validation flags were applied.

BTEX and TPH as Gasoline Analyses—Six field blanks were collected and analyzed for BTEX and TPH as gasoline using EPA SW Method 8020. Analytical results show that BTEX and TPH as gasoline were not detected in any field blank.

TPH as Extractables Analyses—Six field blanks were collected and analyzed for BTEX and TPH as extractables using CAL DHS. Analytical results show that TPH as extractables was not detected in any field blank.

### I.2.3 Equipment Blanks

Equipment blanks provide a measure of the cumulative contamination derived from field sampling equipment, sample transit, storage, and analysis. Equipment blanks were prepared for manual and small automated sampling equipment used to collect environmental samples. One equipment blank was collected every day for each medium sampled by pouring ASTM Type II water into, through, or over a clean piece of sampling equipment and then dispensing the water into prepared sample bottles. Equipment blanks were shipped to the laboratory to be analyzed using the methods required for the environmental samples collected on the same day. All analytical data were reviewed for potential bias introduced from equipment blanks. Table I-5 summarizes the concentrations of the compounds detected in the equipment blanks collected during the SI. The following subsections summarize the compounds and elements detected in these blanks and the impact of any interference on the environmental data quality.

Solvents Analyses—Three equipment blanks were collected and analyzed by MT for solvents using EPA CLP OLMO1. No unacceptable level of contamination was detected in the equipment blanks. Chloroform was detected in two equipment blanks (i.e., 28 and 29  $\mu$ g/L). Since this solvent has not been detected in the associated environmental samples, no data validation flag was applied.

BTEX and TPH as Gasoline Analyses—Five equipment blanks were collected and analyzed by MT for BTEX and TPH as gasoline using SW Method 8020. Analytical results show that BTEX and TPH as gasoline were not detected in any equipment blank.

TPH as Extractables Analysis—Five equipment blanks were collected and analyzed by MT for TPH as extractables using CAL DHS. No TPH was detected in the equipment blanks.

### I.2.4 Field Duplicates

One duplicate environmental sample was collected for every 10 environmental samples, as required by the QAPP. Duplicate sample pairs were collected to ascertain the contribution of variability (i.e., precision) due to environmental media. Twenty soil and two duplicate samples, in addition to six groundwater and one duplicate sample, were collected. One field duplicate soil sample was collected after each 10 environmental samples, as indicated on the chain-of-custody forms. As required by the QAPP, soil samples were collected at specific intervals in the borehole. Specific samples to be sent to the laboratory were selected based on location in the borehole (e.g., at the water table) and health monitoring equipment (i.e., organic vapor analyzer [OVA]). Therefore, duplicate sample selection was less straightforward using these sample selection criteria than simply replicating 1 sample for every 10 collected, since samples were selected only after the drilling had been completed or the monitoring well had been screened. After the split-spoon was retrieved from the borehole, the samples to be screened for VOCs were immediately collected in the sample container. All soil samples to be analyzed by MT were collected using split-spoons equipped with 3-inch brass or stainless-steel sleeves. After the split-spoon sampler was retrieved from the borehole, VOC and TPH sleeves were capped and labeled, and each sample was then shipped to the laboratory in the liner. Therefore, the duplicate concentrations measured by the laboratory reflect the natural matrix variability inherent in the subsurface soils at Site 13 and were not used to assess sample collection precision. As required by the QAPP, water samples were collected to minimize loss of VOCs. The first bailer volume was used to fill the original and replicate sample vials. The next bailer volume was used to fill the bottles for the remaining parameters.

Field RPD values were calculated for compounds and elements detected in concentrations greater than the CRQL or MDL in both replicate pair samples or in one sample. Tables I-6 and I-7 summarize the concentrations of the compounds detected in the soil and groundwater replicate pair collected during the SI.

Solvents Analyses—Nine soil samples and four groundwater samples were collected during the SI and analyzed for solvents by EPA OLMO1 SOW. Two soil samples and two groundwater samples were collected in duplicate. RPD values were not calculated for compounds not detected in both the sample and duplicate sample.

No solvents were detected in the soil and groundwater field duplicates. Precision for solvents collection field duplicates analyses have been determined to be adequate for the SI.

BTEX and TPH as Gasoline Analyses—Twenty soil samples and 22 groundwater samples were collected during the SI and analyzed for BTEX and TPH as gasoline using SW Method 8020. Two soil and three water samples were collected in duplicate. RPD values were not calculated for compounds not detected in both the sample and duplicate samples. TPH as gasoline was detected in one soil field duplicate (i.e., GS6-2) and one groundwater field duplicate (i.e., GW12-6) collected from Site 12. RPD values were 200 percent for TPH as gasoline. These values are attributable to TPH as gasoline concentrations being near the MDL in the field samples. These RPD values include both fluctuations in the sampling and analytical variability.

TPH as Extractables Analyses—Twenty soil samples and 22 groundwater samples were collected during the SI and analyzed for TPH as extractables using CAL DHS. Two soil samples and three groundwater samples were collected in duplicate. RPD values were not calculated for compounds not detected in both the sample and duplicate sample.

No TPH as extractables were detected in the soil and groundwater field duplicates. Precision for solvents collection field duplicates analyses have been determined to be adequate for the SI.

### I.3 LABORATORY QUALITY CONTROL ASSESSMENT

All environmental (i.e., soil and groundwater) samples and field QC blanks (i.e., trip blanks, field blanks, and equipment blanks) collected during the SI at MVMF were analyzed using EPA methods from the following references:

- Test Methods For Evaluating Solid Waste, Physical/Chemical Methods, SW846 (BTEX and TPH)
- Statement of Work for Organic Analysis, Multi-Media, Multi-Concentration, EPA Contract Laboratory Program, OLMO1 August 1991 (solvents).
- Hazardous Materials Laboratory, California Department of Health Services, February 1988 (TPH as extractables).

During the review and evaluation process, 100 percent of the analytical data generated using EPA methods were subject to a systematic and rigorous technical process by examining all analytical QC results and laboratory documentation, following the appropriate guidelines for laboratory data validation. The purpose of this section is to provide an assessment of the QA/QC results from the SI to confirm that the data used in this report meet the DQOs established for this investigation. Both quantitative measures and qualitative assessments will be presented to characterize these data as having sufficient quality to satisfy these objectives. The primary intent of this assessment is to illustrate that data originating from the SI can withstand scientific scrutiny and are technically defensible, and are of a known and acceptable precision and accuracy. All data were validated using the guidelines and specifications described in the following document:

• Laboratory Data Validation Functional Guidelines Evaluating Organics Analyses, EPA CLP, February 1988.

### I.3.1 Organic Analyses

Environmental (i.e., soil and groundwater) samples and field QC blanks (i.e., trip blanks, field blanks, and equipment blanks) collected during the SI were submitted to MT for solvents, BTEX, TPH as gasoline, and TPH as extractables analyses. A data quality assessment is presented in the following subsections.

### I.3.1.1 Solvents Analyses (EPA OLMO1 SOW)

Nine soil samples, 4 groundwater samples, and 13 field QC blanks (i.e., trip blanks, field blanks, and equipment blanks) were collected and analyzed by MT for solvents (i.e., vinyl chloride, chloroform, 1,1,1-trichloroethane, trichloroethene, 1,2-dichloroethane, tetrachloroethane, and carbon tetrachloride) using EPA OLMO1 SOW. Data quality was evaluated using the guidelines and control limits specified for holding times, tuning and mass calibration results, initial and continuing calibration verification, method blanks, system monitoring compounds recoveries, internal standard areas, and MS/MSD results. The VOC data validation worksheets are presented in Table I-8.

Holding Times—Holding times are used to ascertain the validity of results based on the holding time of the sample from the time of collection to the time of analysis. MT was required by the QAPP and analytical methods to meet holding times of 7 days for unpreserved water samples, 14 days for preserved (i.e., sufficient hydrochloric acid to lower the pH to 2) water samples, and 14 days for soil samples collected for solvents analysis.

Analysis of samples that have exceeded the method-recommended holding times may result in the following: 1) concentrations of compounds that would have been detected ordinarily are undetected due to chemical transformation, compound volatilization, or biodegradation; 2) reported concentrations lower than those originally present due to the factors previously stated; or 3) reported concentrations greater than those originally present in the sample due to external contamination of water samples or changes in soil moisture content. Based on an evaluation of all environmental samples and field QC blanks analyzed for solvents, all holding time criteria were met.

Tuning and Mass Calibration Results—The first step in the calibration of the GC/MS system is to ensure correct mass calibration, mass resolution, and mass transmission. This was accomplished, in addition to a sensitivity check, using p-bromofluorobenzene (p-BFB) injected at a 50 ng concentration, as required by the SOW protocol. This standard was analyzed every 12 hours to ensure that the GC/MS was tuned correctly. Based on an evaluation of the

ionization and fragmentation criteria, in addition to the instrument tune frequency, all p-BFB tuning and mass calibration criteria requirements were met.

Initial Calibration Results—Compliance requirements for satisfactory instrument calibration have been established to ensure that the instrument is capable of producing acceptable quantitative data. Calibration of each GC/MS used to analyze the samples collected during the SI were established and validated by injecting standards at five concentrations, spanning the expected sample concentration range. Initial calibration was conducted after the GC/MS tune criteria were met and before any samples were analyzed to determine the instrument sensitivity and the linearity of each compound. The linearity is important to ensure reasonable quantitative results over the range of the curve. Following initial calibration, all compounds were evaluated to verify the validity of the calibration. Specifically, the relative response factors (RRFs) and percent relative standard deviation (%RSDs) for all solvents were evaluated to verify the validity of the initial calibration. Calibration criteria requirements (i.e., greater than 0.050 and less than 30 percent for RRFs and %RPDs, respectively) for solvents were presented in the Laboratory Data Validation Functional Guidelines for Evaluating Organics Analyses. All criteria requirements were met.

Continuing Calibration Verification Results—A check of the calibration curve was conducted before and after environmental samples were analyzed each day. The first daily standard in the BFB tuning period was used for quantitation of all sample analyses performed during the 12-hour period. The continuing calibration verification (CCV) was used for quantitation and to verify that the working curve is still valid. The CCV standard of the GC/MS system is evaluated based on the magnitude of the RRFs and percent difference (%D) between the average RRF of each compound for the initial calibration and the RRF of that compound in the CCV standard. CCV criteria requirements (i.e., greater than 0.050 and within ±25 percent for RRFs and %Ds, respectively) for solvents were presented in the Laboratory Data Validation Functional Guidelines for Evaluating Organics Analyses. Based on an evaluation of the CCVs conducted for solvents analyses, all criteria requirements were met.

Internal Standard Summaries—Three internal standards (ISs) (i.e., bromochloromethane, 1,4-difluorobenzene, and chlorobenzene-d<sub>5</sub>) were added to all calibration standards, environmental samples, and QC blanks immediately before analysis as indicators of instrumental operating variations. The concentration of solvents detected in each sample was calculated with reference to the response factor (RF) of the appropriate IS for that compound. Internal standard area requirements are described in the EPA OLMO1 SOW. Based on an evaluation of all analyses, all internal areas were within the control limits.

Recoveries—Three deuterated compounds Compounds Monitoring System (i.e., 1,2-dichloroethane-d<sub>4</sub> toluene-d<sub>8</sub>, and p-BFB) were added to each calibration standard, environmental sample, and laboratory and field QC sample immediately before analysis. Surrogate compounds spiked into field samples provide information on the efficiency of all steps of the GC/MS method in recovering these compounds from the individual environmental sample matrices. Since surrogate recoveries were spiked into every environmental sample, they were the primary tool used to determine if matrix interferences were present during solvent analyses. The OC limits for recovery of all surrogates for soil and water samples were those established for the EPA CLP SOW. All surrogate percent recoveries were within the applicable control limits for environmental samples. Tables I-9 and I-10 summarize the surrogate recovery results for the soil and water samples that were evaluated, respectively.

Method Blank Results—One method blank analysis was conducted for each analytical lot of environmental samples analyzed for solvents. Each method blank was evaluated for contaminants that prevent accurate quantitation of a target compound. If any problems with any blank existed, all data associated with the case were carefully evaluated to determine whether an inherent variability in the data for the case exists, or if the problem is an isolated occurrence that would not affect the data. Based on an evaluation of all method blanks analyzed for solvents using EPA OLMO1 SOW, no solvents were detected at a level and frequency that might bias the analytical results, except for chloroform. This solvent was noted in the method blank (i.e., VBLK3500) analyzed on July 25, 1995. No validation flag was applied, since this solvent was not detected in the associated environmental samples.

Matrix Spike/Matrix Spike Duplicate Results—MS/MSD analyses were conducted to assess the accuracy and precision of the laboratory and to evaluate the matrix effect of the sample upon the analytical methodology based upon the percent recovery of each compound. Accuracy was expressed as the percent recovery of the spike compounds. Precision was expressed as the RPD of the concentrations of the spike compounds in the MS/MSD samples. The control limits for percent recoveries in soil and water samples are described in the QAPP. MS/MSDs were evaluated to verify that one MS/MSD analysis was conducted for every 20 environmental sample received by the laboratory, that these analyses were conducted on environmental samples only, and that the recovery and difference results did not indicate systematic laboratory control problems. Table I-11 summarizes the MS/MSD results for soil samples.

All recovery and RPDs reviewed values for soil solvents MS/MSDs were within the EPA CLP advisory control limits. No MS/MSD analyses were conducted for groundwater samples collected during the SI.

### I.3.1.2 BTEX and TPH as Gasoline Analyses (EPA Method 8020)

Twenty-two soil samples, 14 groundwater samples and 9 field QC blanks (i.e., trip blanks, field blanks, and equipment blanks) were collected and analyzed by MT for BTEX and TPH as gasoline using EPA Method 8020. Data quality was evaluated using the guidelines and control limits specified for holding times, initial and continuing calibrations, method blanks, surrogate internal standards, surrogate recoveries, and MS/MSD results. The BTEX and TPH as gasoline data validation worksheets are presented in Table I-12.

Holding Times—The objective is to ascertain the validity of results based on the holding time of the sample from the time of collection to the time of analysis. MT was required by the QAPP and analytical method to meet holding times of 14 days for soil and water samples. Based on an evaluation of all environmental samples and field QC blanks analyzed for BTEX and TPH as gasoline using EPA SW846 Method 8020, all holding time criteria were met.

Initial Calibration Results—Compliance requirements for satisfactory instrument calibration have been established to ensure that the instrument is capable of producing acceptable quantitative data. Calibration of each GC used to analyze the samples collected during the SI were established and validated by injecting standards at eight concentrations, spanning the expected sample concentration range. One of the standard concentrations was at a concentration near, but above, the method detection limit. Initial calibration was conducted before any samples were analyzed to determine the instrument sensitivity and the linearity of each compound. Following initial calibration, all compounds were evaluated to verify the validity of the calibration. Specifically, the response factors were calculated for BTEX and the results were used to establish the calibration curves. These calibration curves were used for BTEX, TPH as gasoline, and surrogate quantitation. All initial calibration criteria were met.

Continuing Calibration Standard Results—A check of the calibration curve was conducted before and after environmental samples were analyzed each day. The continuing calibration standard (CCS) was used to verify that the working curve is still valid. The CCS of the GC system was evaluated based on the magnitude of the instrument response for BTEX. The instrument response for BTEX and TPH as gasoline from the CCS must agree within  $\pm 15$  percent with the predicted response, and all preceding standard in an analysis sequence should fall within the daily retention time window established by the first standard of the sequence. Based on an evaluation of the CCSs conducted for BTEX and TPH as gasoline analyses, all criteria were met.

Surrogate Recoveries—One surrogate (i.e.,  $\alpha, \alpha, \alpha$ -trifluorotoluene) was added to each calibration standard, environmental sample, and laboratory and field QC sample immediately before analysis. Surrogate compounds spiked into field samples provide information on the efficiency of all steps of the GC method in recovering this compound from the individual environmental sample matrices. Since  $\alpha, \alpha, \alpha$ -trifluorotoluene was spiked into every environmental sample, it was the primary tool used to determine if matrix interference was present during BTEX and TPH as gasoline analyses. The QC limits for recovery of  $\alpha, \alpha, \alpha$ -trifluorotoluene in soil and water samples were submitted by MT for each analytical run (i.e., lower control limit and upper control limit). All surrogate recoveries were within the

recommended control limits. Tables I-13 and I-14 summarize the surrogate recovery results for soil and water samples, respectively.

Method Blank Results—One method blank analysis was conducted for each analytical lot of environmental samples analyzed for BTEX and TPH as gasoline. Each method blank was evaluated for contaminants that prevent accurate quantitation of a target compound. Based on an evaluation of all method blanks analyzed for BTEX and TPH as gasoline using EPA Method 8020, no BTEX and TPH as gasoline were detected in the method blanks.

Matrix Spike/Matrix Spike Duplicate Results—MS/MSD analyses were conducted to assess the accuracy and precision of the laboratory and to evaluate the matrix effect of the sample upon the analytical methodology based upon the percent recovery of each compound. Accuracy was expressed as the percent recovery of the spike compound. Precision was expressed as the RPD of the concentration of the spike compound in the MS/MSD samples. The control limits for percent recoveries in soil and water samples were described in the QAPP. MS/MSDs were evaluated to verify that one MS/MSD analysis was conducted for each 20 environmental samples received by the laboratory, that these analyses were conducted on environmental samples only, and that the recovery and difference results did not indicate systematic laboratory control problems. Table I-15 and I-16 summarize the MS/MSD results for soil and groundwater samples, respectively.

Five MS/MSD analyses were validated for soil samples collected during the SI. All MS/MSD recovery and RPD values were within control limits. Two MS/MSD analyses were conducted using groundwater samples collected during the SI. All MS/MSD and RPD values were within the control limits.

## I.3.1.3 TPH as Extractables Analyses (CAL DHS)

Twenty soil samples, 22 groundwater samples, and 11 field QC blanks were collected during the SI and analyzed for TPH using CAL DHS. Data quality was evaluated using the guidelines and control limits specified for holding times, instrument calibration, method blanks,

surrogate recovery results, MS/MSDs, and laboratory control sample. The data validation worksheets are presented in Table I-17.

Holding Times—MT was required to meet an extraction holding time of 7 days for soil samples and water samples. All analyses were required within 40 days after collection. Based on an evaluation of all environmental samples and field QC blanks extracted and analyzed for TPH, all holding time criteria were met.

Instrument Calibrations—Calibration of the GC used to analyze the samples collected during the SI for TPH as extractables was established by injecting standards at six concentrations, spanning the expected sample concentration range. Initial calibration was conducted before any samples were analyzed to determine the instrument sensitivity. The instrument responses were used to establish the calibration curve. The calibration curve was fitted by a linear equation. This equation was used for TPH as extractables quantitation.

Based on an evaluation of the initial calibration conducted for TPH as extractables analyses, all criteria requirements were met.

Calibration Verification Results—Daily and every 10 samples, a calibration check standard was analyzed. Following the standard analyses, percent recovery values were calculated for each element to verify that the initial calibration remained acceptable. Calibration check standard criteria requirements included 85 to 115 percent, as required by the CAL DHS method. Based on an evaluation of the continuing calibrations conducted, all percent recovery values were within control limits.

Method Blank Results—One method blank was extracted and analyzed with each lot of samples analyzed during the SI for TPH as extractables. Based on an evaluation of all method blanks analyzed, no TPH as extractables was detected in the method blanks.

Surrogate Recoveries—One surrogate compound (i.e., pentacosane) was added to each calibration standard, environmental sample, and laboratory and field QC sample immediately

before TPH as extractables analysis. Surrogate compounds spiked into field samples provide information of the efficiency of all steps of the GC method in recovering this compound from the individual environmental sample matrices. Since pentacosane was spiked into every environmental sample, it was the primary tool used to determine if matrix interference was present during TPH as extractables analysis. All surrogate recoveries were within the recommended control limits. Tables I-18 and I-19 summarize the surrogate recovery results for soil and water samples, respectively.

Matrix Spike/Matrix Spike Duplicate Results—MS/MSD analyses were conducted to assess the accuracy and precision of the laboratory and to evaluate the matrix effect of the sample upon the analytical methodology based upon the percent recovery of each compound. Accuracy was expressed as the percent recovery of the spike compounds. Precision was expressed as the RPD of concentration of the spike compound in the MS/MSD samples. The control limits for percent recoveries are 85-115 percent for TPH as extractables in water samples, and 75-125 percent for TPH as extractables in soil samples. The acceptable RPD upper limits applied to each analytical lot for TPH water is 20 percent and for TPH as extractables in soil samples analyses is 30 percent. MS/MSD samples were evaluated to verify that 1 spiked sample analysis was conducted for 20 environmental samples received by the laboratory, that these analyses were conducted on environmental samples only, and that the recovery and difference results did not indicate laboratory control problems. Tables I-20 and I-21 summarize the MS/MSD results for soil and groundwater samples.

Two MS/MSD analyses were conducted using soil samples collected during the SI. Two recoveries (of 4 reviewed values) calculated from the TPH soil MS/MSD analyses were greater than the 125 percent limit. The MSD recovery of TPH as extractables was 136 percent in GS01-1 and 131 percent in GS13-1-1 MS. The laboratory check sample (LCS) and surrogate recoveries were within acceptable criteria. All RPDs were within the control limits. The fact that high recoveries were observed supports the idea that these deviations were the result of heterogeneity rather than a problem in spiking or an analysis problem. Therefore, no action was taken based on MS/MSD results. One MS/MSD analysis was conducted using groundwater samples collected during the SI. All MS/MSD results were within the control limits.

Laboratory Check Sample Analysis—One LCS was extracted and analyzed with each analytical lot of soil and groundwater samples analyzed by MT. The LCS serves as a monitor of the overall accuracy and performance of all steps in the analysis, including sample preparation. The recovery results of each LCS analyzed were evaluated against 80 to 120 percent for TPH as extractables control limits. Based on an evaluation of all LCS analyses, the percent recoveries were within the control limits.

## I.3.4 Assessment Summary

During the SI, 58 samples were collected, resulting in an analytical data base of more than 800 discrete analyses (i.e., compounds). The SI field effort provided 100 percent of the planned samples to complete the assessment. The primary objective of this SI QA program was to assess and summarize the quality and reliability of the data for the intended use and to document factors that may affect the usability of the data. Technical criteria examined during the data validation phase included:

- Holding times
- Instrument calibration
- Blanks
- Surrogate recoveries
- MS/MSD analyses
- Field duplicates
- Internal standard performance
- GC/MS tuning
- Compound quantitation and reported detection limits.

For the purposes of this SI, sample data have met all criteria for their intended use.

DESCRIPTION OF CHANGE PHO	ME (614)793-7600
Sand Pack was brought up to I toot above	the top of the screen
instead of 2th	
AUSTIFICATION	
Two ted of send would have brought up	the bentante seal
too close to the our tree and there would	not be enough room
for growth, and lowering the well would only one foot above the top of the screen	put the water table
only one foot above the top of the screen	
VFACT OF IMPLEMENTING REQUEST	
Based on the amount of room at the top and the need for 2 feet of bentonite se	or the water take
one foot of grout, one foot of send was the	e better alternative to
lowering the well
